COMP 105 Homework: Standard ML Modules

Due Sunday, December 11 at 11:59 PM.

The purpose of this assignment is threefold:

- To get some practice with Standard ML modules
- To use Standard ML modules to put together a nontrivial program.
- To see how to reuse code that depends not just on other values, but also on other types.

Setup

The code in this handout, together with a compile script, can be had by

```
    git clone linux.cs.tufts.edu:/comp/105/git/ttt
```

Pair Problems

This homework has three problems: 1, A, and B.

Contents

- Setup
- Pair Problems
- Part I: ML modules finger exercises
- Part II: Playing adversary games
  - The idea behind the Abstract Game Solver (AGS)
  - Basic data in the problem: Players and outcomes
  - Specification of an abstract game
  - Adversary game problems
    - Problem A: Implement Tic-Tac-Toe
    - Testing your code: using the AGS with Tic-Tac-Toe
    - Problem B: Building an AGS
    - A common mistake to avoid when debugging your AGS
    - Using your AGS to play other games
  - Descriptions of the games
    - Tic Tac Toe
    - Nim
    - Connect 4
- Extra Credit
- What to submit
- How to submit
- Acknowledgments
- Appendix I: Two ways to compile Standard ML modules
  - Compiling Standard ML modules using Moscow ML
  - Compiling Standard ML to native machine code using MLton
- Appendix II: The code we give you and how to get it
- Appendix III: How your work will be evaluated
  - Interface design and modular programming
  - Mutability
  - Evaluation criteria
    - Interface design and documentation
    - Program structure
    - Performance and correctness
Part I: ML modules finger exercises

1. Data structures (Difficulty *, Time **). A heap is a collection of elements with an operation that quickly finds and removes a minimal element. (The heap assumes that a total order exists on the elements; a minimal element is an element of the heap that is at least as small as any other element. A heap may contain more than one minimal element, in which case it is not specified which such element is removed.)
   a. Design an abstraction for representing heaps in ML. Your abstraction may be mutable or immutable. Formalize your abstraction by giving an ML signature HEAP describing the abstraction. Be sure to
      ◇ Define two abstract types: one to represent a heap and one to represent an element.
      ◇ Identify each operation as a creator, producer, mutator, or observer (as described in Section 2.4.2 on page 100 of Ramsey)
      ◇ Specify what each operation does, either using informal English, algebraic laws, or both
   The heap assumes that values of the element type are totally ordered; be sure to expose that total order in the interface. Put your signature into a file called heap-sig.sml. You will need to compile it with the -toplevel option, e.g.,

   mosmlc -toplevel -c heap-sig.sml

   Notice that for this part of the problem you write no code. All you write is the interface.

   b. Use your abstraction to implement heap sort. That is, write a functor HeapsortFn that takes a structure matching signature HEAP and produces a structure that contains a function that sorts a list of elements by inserting all the elements into a heap, then removing them one by one until the heap is empty.
      ◇ Give your functor an explicit result signature, paying careful attention to type revelation.
      ◇ You need not implement HEAP. This is the whole point!
   Put your HeapsortFn functor into a file called heapsort.sml. You will need to compile it with the -toplevel option, e.g.,

   mosmlc -toplevel -c heap-sig.ui heapsort.sml

   Because the heapsort.sml refers to signature HEAP, you must pass it the heap-sig.ui file where signature HEAP is defined. You will have produced heap-sig.ui by compiling heap-sig.sml.

Part II: Playing adversary games

In problems A and B below, you will implement and use a system for playing simple adversary games. The program will show game configurations, accept moves from the user, and choose the best move.

The system is based on an abstract game solver (AGS) which, given a description of the rules of the game, will be able to select the best move in a particular configuration. An AGS is obtained by abstracting (separating) the details of a particular game from the details of the solving procedure. The solving procedure uses exhaustive search: it tries all possible moves and picks the best. Such a search can solve games of complete information, provided the configuration space is small enough. And the search is general enough that we can abstract away details of many games, separating the implementation of the solver from the implementation of the game itself.

Separating game from solver in such a way that a single solver can be used with many games requires a carefully designed interface. In this problem, we give you such an interface, which is specified using the SML signature GAME. (The signature was designed by George Necula and modified by Norman Ramsey.)

The GAME signature declares all the types and functions that an Abstract Game Solver must know about a game. The signature is general enough to cover a variety of games. Even details like ``the players take turns'' are considered to be part of the rules of the game—such rules are hidden behind the GAME interface, and the AGS operates correctly no matter what order
players move in. (You could even implement a solitaire as a "two-player" game in which the second player never gets a turn!)

You will use two-player games in the last two parts of this assignment: implement a particular game and implement an AGS of your own.

The idea behind the Abstract Game Solver (AGS)

As players move, the state of a game moves from one configuration to another. In any given configuration, our solver considers all possible moves. After each move, it examines the resulting configuration and tries all possible moves from that configuration, and so on. In each configuration, the solver assumes that the player plays perfectly, that is, whenever possible the player will choose a move that forces a win.

This method ("exhaustive search") is suitable only for very small games. Nobody would use it for a game like chess, for example. Nevertheless, variations of this idea are used successfully even for chess; the idea is to stop or "prune" the search before it goes too far. Alpha-beta pruning is a more advanced strategy for solving this kind of problem. You may have seen it before in some of your other classes. You are free to use this more advanced implementation strategy in your solver, but you are not required to do so.

Basic data in the problem: Players and outcomes

Representation is the essence of programming. We start by describing basic representations for the essential facts we assume about each game:

1. There are two players.
2. A game ends in an outcome: either one of the players has won, or the outcome is a tie.

The representations of these central concepts are exposed, not abstract. They are given by the signature PLAYER.

```sml
signature PLAYER = sig
datatype player  = X | O  (* 2 players called X and O *)
datatype outcome = WINS of player | TIE

val otherplayer : player -> player   (* Returns the other player *)
val toString    : player -> string
val outcomeToString : outcome -> string
end
```

The signature `player` also includes some functions that compute with players and outcomes. Here's the implementation of `PLAYER` in a structure called `Player`.

```sml
structure Player :> PLAYER = struct
datatype player  = X | O
datatype outcome = WINS of player | TIE

fun otherplayer X = O
| otherplayer O = X

fun toString X = "X"
| toString O = "O"

fun outcomeToString TIE = "Tie"
| outcomeToString (WINS p) = toString p ^ " wins"
end
```

Part II: Playing adversary games
Although it might seem overly pedantic, we prefer to isolate details like the player names and how to convert them to a printable representation.

To refer to Player types, constructors, and functions, you will use the ``fully qualified” ML module syntax, as in the examples Player.otherplayer p, Player.X, Player.O, and Player.WINS p. The last three expressions can also be used as patterns.

**Specification of an abstract game**

The AGS can play any game that meets the specification given in signature GAME. This signature gives a contract for an entire module, which subsumes the contracts for all its exported functions.

```sml
<game-sig.sml>=
signature GAME = sig
    structure Move : sig (* information related to moves *)
    eqtype move             (* A move (perhaps a set of coordinates) *)
    exception Move          (* Raised (by makemove & fromString) for invalid moves *)
    val fromString : string -> move (* converts a string to a move; If the string does not correspond to a valid move, fromString raises Move *)
    val prompt : Player.player -> string (* Given a player, return a request for a move for that player *)
    val toString : Player.player -> move -> string (* Returns a short message describing a move. Example: "Player X moves to ...". The message cannot contain a newline. *)
end

val toString : config -> string (* Returns an ASCII representation of the configuration. The string must show whose turn it is. *)

val initial : Player.player -> config (* Initial configuration for a game when "player" is the one to start. We need the parameter because the configuration includes the player to move. *)

val whoeturn : config -> Player.player (* Extracts the player whose turn is to move from a configuration. We need this function because the solver may need to know whose turn it is, and the solver does not have access to the representation of a configuration. *)

val makemove: config -> Move.move -> config (* Changes the configuration by making a move. The player making the move is encoded in the configuration. Be sure that the new configuration knows who is to move. *)

val outcome : config -> Player.outcome option (* If the configuration represents a finished game, return SOME applied to the outcome. *)
```

Basic data in the problem: Players and outcomes
If the game isn't over, return NONE. *)

val finished : config -> bool
(* True if the configuration is final. This might be because one player has won, or it might be that nobody can move (which would be considered a tie). *)

val possmoves : config -> Move.move list
(* A list of possible moves in a given configuration. ONLY final configurations might return nil. This means that a configuration which is not final MUST have some possible moves. In other words, part of the contract is that if 'finished cfg' is false, 'possmoves cfg' must return non-nil. *)

end

Defines config, finished, GAME, initial, makemove, Move, outcome, possmoves, toString, whoseturn (links are to index).

This is a broad interface. For example, there are three different ways to tell if a game is over!

Adversary game problems

Problem A: Implement Tic-Tac-Toe

A. Implement ``Tic-Tac-Toe.'' (Difficulty **, Time ***) More precisely, implement a module TTT matching signature GAME that describes Tic-Tac-Toe. If you are unfamiliar with Tic-Tac-Toe (elsewhere called ``Noughts and Crosses''), you can find an explanation at the end of this assignment. Call your structure TTT, put it in the file ttt.sml, and use the following pattern :

<template for ttt.sml>=
structure TTT :> GAME =
  struct
    structure Move = struct
      type move = ... (* or use a datatype *)
      exception Move
      ...
    end

    type config = ... (* or use a datatype config = *)

    fun initial p = ...
    fun whoseturn c = ...
    ...
    ... and so on for all the values in GAME ...
  end

Defines TTT (links are to index).

Note the use of :>, which means that the only access to the types is through the functions in the GAME signature.

When writing TTT, you must define all types and values mentioned in the signature GAME, and all values must have the types specified. You might want to define additional values, which you will be able to use as helper functions. These functions cannot be called from anyone else's code: because TTT is forced to have signature GAME, the functions are not visible outside the TTT module, and therefore no other code can depend on them.

Specification of an abstract game
So we can test your code, we insist that you use the following names of squares in Move.toString and Move.fromString:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>upper left</td>
<td>upper middle</td>
<td>upper right</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>-----------</td>
</tr>
<tr>
<td>middle left</td>
<td>middle</td>
<td>middle right</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>-----------</td>
</tr>
<tr>
<td>lower left</td>
<td>lower middle</td>
<td>lower right</td>
</tr>
</tbody>
</table>

You should always print and recognize these full names. If you wish, you may also recognize the abbreviations ul, um, ur, ml, m, mr, ll, lm, and lr in the function Move.fromString.

Here are step-by-step instructions:

a. Choose how you will represent the state of the game (i.e., define config). This step is crucial because it determines how complex your implementation will be. There are many possible representations; any one is OK provided you are able to implement the functions required by the signature. Choose a representation that will make it easy to implement makemove, possmoves, and outcome.

The AGS cannot possibly depend on your choice of representation (the ML module system guarantees it), so you are free to choose whatever representation you like. Even more important, you can change your representation at any time, and no code outside your own module will be affected. If you have any difficulty implementing the functions in the GAME interface, you should change your representation—or at least think about it.

Document your representation by stating any invariants that it satisfies, and explain how your representation relates to the abstraction of the tic-tac-toe grid.

You might be tempted to use mutable data to represent game state. Don't! The contract of the GAME interface requires that any value of type config be available to the AGS indefinitely. Mutating a configuration is not safe.

If you think you might want immutable arrays, check out the Vector structure (see the ML supplement). (You can find out what's in any ML structure by typing, e.g., open Vector at the interactive prompt, or you can consult the Standard Basis documentation. You can also use Moscow ML's help system, e.g.,

- help "Vector";

If you get interested in vectors, don't overlook the function Vector.tabulate.)

One more thing. You may be tempted to start out by representing the contents of a square on the board using 0 and 1 or other arbitrary values. If you go this route, why not use Player.player option? It will make your program more elegant and easier to understand.

b. Choose a representation for moves. That is, write move. Everything said for configurations applies here also, but this choice seems less critical.

c. Declare the exception Move.

d. Write the function initial.

e. Write the function whoseturn.

f. Write makemove. The contract requires it to be Curried.

g. Write outcome. If the configuration is not final and nobody has won, return NONE.

Hints for Tic-Tac-Toe:

- You could write a function which checks lines, another that checks columns and finally one that checks diagonals. Then outcome could call these functions with the right parameters.
You could try pattern matching. Standard ML supports pattern matches on vectors by, e.g.,
case a of
  #[x, y, z] => ...

h. Write finished. This function should return true if somebody has won or if no move is possible (everybody is
stuck). Be smart and use another function to do most of the work.
i. Write possmoves. This function must return a list of the possible moves (in no particular order). It is in
everybody's interest that the list have no duplicates. If the game is over, no further moves are possible, and
possmoves must return nil. (In this case, according to contract, finished must return true.)

If you want to be clever, you can exploit rotation and reflection symmetries to prune the list returned by
possmoves. You may be surprised how much difference this makes to performance.
j. Create a data structure that associates each move with one or more representations of that move as strings. This data
structure will be a single point of truth, and it will ensure that Move.fromString and Move.toString cannot
possibly be inconsistent, even if you make a mistake in their implementations. To get full credit for this problem,
your code must provide this guarantee by ensuring there is a single point of truth.

k. Using your data structure from the previous step, write Move.toString. This function must return a string of the
form "Player... moves to ..." which does not end in a newline. You can build your strings using concatenation (^)
and exported functions from other modules (e.g. Player.toString). To convert integer values to strings you
can use the function Int.toString.
l. Write toString. You must return a simple ASCII representation of the state of the game configuration. The value
should end in a newline. Don't forget to include the player whose turn it is to move. Give us more than a simple list
of numbers. You can print a nice little "ASCII graphics" layout using only a few characters. To get you started, here
is some untested sample code to print a row; it has type player option list -> string:

<sample function rowString>=
local
  fun boxString (SOME p) = Player.toString p
  | boxString (NONE ) = " 
  in
  fun rowString []                = "\n
  | rowString (box :: boxes) = "| " ^ boxString box ^ " " ^ rowString boxes
end

Move.toString and toString are not involved in the correctness of the AGS; they are used by the interactive
player to show you what's happening. The better your output, the more fun it will be to play. You can see a simple
sample by running /comp/105/bin/ttt.

m. Write Move.prompt. It takes the player whose turn it is to move, and it returns a prompt message (without
newline) asking the specified player to give a move in the format we specified (naming the square).
n. Write Move.fromString. This function should take a string (which is probably the reply given after a call to
Move.prompt, and it should return the move corresponding to that string. If there is no such move, it should raise
an exception.

You should try to write Move.fromString in such a way that Move.fromString and Move.toString
cannot possibly be inconsistent, even if you make a mistake. Because we give you a lot of freedom, it is hard to
specify precisely what it means to be consistent, but here is a rough specification:

For any move m, there should be an i and n such that m is equal to Move.fromString
(String.extract (Move.toString m, i, SOME n)).

Be sure to try your functions on simple configurations.

Hints: You may find it useful to define a structure Grid that you can use to represent a square or rectangular array of
values of type 'a. Defining suitable analogs of map and fold on the grid will help, as will functions to extract sub-grids
(rows and columns).

The most common mistake on this problem is to permit players to continue to move even when the game is over.
Bob Harper’s code for Tic-Tac-Toe is 146 lines of Standard ML. I have a slicker version at only 87 lines—and it is four times faster. It works by exploiting bit-level parallelism using the Word structure and by flagrantly disregarding most of the hints given above.

**Testing your code: using the AGS with Tic-Tac-Toe**

To build a version of the AGS for ``Tic-Tac-Toe” you must use the following command:

```ml
<example of creating a game-specific AGS>
structure TTTAgs = AgsFun(structure Game = TTT)
```

Of course, I can’t do any of this until I compile the relevant files using the provided `compile` script and then use the Moscow ML `load` function to get access to `AgsFun` and `TTT`. Here is an example:

```ml
<transcript from an actual session>
[D->]
: sunfire62: ./compile
: sunfire62: mosml
Moscow ML version 2.10-2 (Tufts University, February 2011)
Enter `quit();' to quit.
- load "ags";
  > val it = () : unit
- load "ttt";
  > val it = () : unit
- structure TTTAgs = AgsFun(structure Game = TTT);
  > structure TTTAgs :
      {structure Game :
        {structure Move :
          {type move = move,
           exn Move : exn,
           val fromString : string -> move,
           val prompt : player -> string,
           val toString : player -> move -> string},
        type config = config,
        val finished : config -> bool,
        val initial : player -> config,
        val makemove : config -> move -> config,
        val outcome : config -> outcome option,
        val possmoves : config -> move list,
        val toString : config -> string,
        val whoseturn : config -> player,
        val bestmove : config -> move option,
        val forecast : config -> outcome
      },
      val bestmove : config -> move option
    }
```

This functor application creates a structure that implements the AGS signature:

```ml
<ags-sig.sml>
signature AGS = sig
  structure Game : GAME
    (* Given a configuration, returns the most beneficial move for the player to move *)
    val bestmove : Game.config -> Game.Move.move option
    (* Given a configuration, returns the best possible outcome for the player whose turn it is, assuming opponent plays optimally *)
    val forecast : Game.config -> Player.outcome
end
```

Defines AGS, bestmove, forecast, Game (links are to index).
The function \texttt{bestmove} returns the best move in a configuration, or \texttt{NONE} if no move is possible, i.e., the configuration is final. The function \texttt{forecast} predicts the outcome from a configuration if both players make perfect moves.

These functions can be \textit{slow} because the AGS tries all possible combinations of moves. Be patient.

We have also provided you an interactive player (in the file \texttt{play.sml}). It uses the AGS so you must instantiate it to the Tic-Tac-Toe AGS using the following command:

\begin{verbatim}
structure P = PlayFun(structure Ags = TTTAgs);
\end{verbatim}

Again, to get \texttt{PlayFun} you will have to load the right module:

\begin{verbatim}
> val it = () : unit
> structure P = PlayFun(structure Ags = TTTAgs);
> structure P :
{structure Game : ...
  exn Quit : exn,
  val getamove : player list -> config -> move,
  val play : (config -> move) -> config -> outcome}
\end{verbatim}

The structure this application creates implements the following signature:

\begin{verbatim}
signature PLAY = sig
  structure Game : GAME
  exception Quit
  val getamove : Player.player list -> Game.config -> Game.Move.move
    (* raises Quit if human player refuses to provide a move *)
  val play : (Game.config -> Game.Move.move) -> Game.config -> Player.outcome
end
\end{verbatim}

Defines \texttt{Game}, \texttt{getamove}, \texttt{PLAY}, \texttt{play}, \texttt{Quit} (links are to index).

The function \texttt{getamove} expects a list of players for which the computer is supposed to play (the computer might play for X, for O, for both or for none). The return value is a function which the interactive player will use to request a move given a configuration. The idea is that the function returned will ask the AGS for a move if the computer is playing for the player to move, or will prompt the user and convert the user's response into a move.

The function \texttt{play} expects an input function (one built by \texttt{getamove}) and a starting configuration. This function then starts an interactive loop printing the intermediate configurations and prompting the users for moves (or asking the AGS where appropriate). One example is:

\begin{verbatim}
val computerxo = P.getamove [Player.X, Player.O]
  (*Computer plays for both X and O *)
val computero = P.getamove [Player.O]
  (*Computer plays only O *)
val cnfi = TTT.initial Player.X
  (* Empty configuration with X to start *)
val frustration = P.play computero
  (* We play against the computer *)
val _ = frustration cnfi
  (* A frustrating exercise *)
\end{verbatim}
Problem B: Building an AGS

B. Implement an Abstract Game Solver (Difficulty ***). Given a configuration, an AGS should compute the benefits of all possible moves and pick the best one. More precisely, given a configuration and a player, the AGS assigns a benefit to that player of that configuration. A final configuration in which X has won should have maximum benefit to X and minimum benefit to O, and vice versa. Ties should have intermediate and equal benefit to both players. We compute the benefit of an intermediate configuration by looking at all possible moves and the benefits of the resulting configurations.

There are a variety of ways to view benefits; for example, we could assign larger benefits to winning quickly, and so on. For this assignment, however, it will be sufficient to consider three levels of benefits:

- Player to move can force a win
- Both players can force a tie
- Player to move can be forced to lose by his adversary

For extra credit you can prove that one of these three situations must hold in any game described by the GAME signature, provided that the game is deterministic and is guaranteed to terminate after finitely many moves.

Write an AGS using the following template:

```ml
<template for functor AgsFun> =
functor AgsFun (structure Game : GAME) :> AGS
where type Game.Move.move = Game.Move.move
and type Game.config = Game.config
= struct
structure Game = Game

fun bestresult conf = ...
fun bestmove conf = ...
fun forecast conf = ...
end

Defines AgsFun, bestmove, bestresult, forecast, Game (links are to index).
```

Note how annoying the where type declarations are: they look tautological, but they're not. Complain to Dave MacQueen and Bob Harper.

We recommend you create a helper function bestresult with type

```ml
val bestresult : Game.config -> Game.move option * result
```

where result is a representation you choose. The idea is that bestresult conf = (bestmove, whathappens) where

- If the player can't move, bestmove is NONE.
- If the player can move, bestmove is SOME m, where m is the best possible Game.move for the player in this configuration.
- Value whathappens explains what the AGS predicts is the outcome of the game if both players play perfectly. It suffices to use a result of type Player.outcome, but you can play around with this one some—for example, you might want to return an outcome like "Player X wins in 3 moves." This would help you build an aggressive AGS.

You might be tempted to use a "relative" outcome like "Win, Lose, or Tie." This can be made to work, but it is harder to get right, especially in games where players don't always take turns.
In order to make \texttt{bestresult} work, you'll need some recursive calls. You'll also want a helper function that lets you compare the benefits of different outcomes, so \texttt{bestresult} can choose the most desirable outcome for the current player.

\textit{Hints:}

- To speed up the AGS, you may want to stop the search as soon as you find a forced win.
- Do \textbf{not} assume that players take turns, that the last player to move always wins, or any other properties of Tic-Tac-Toe. Use \texttt{whoseturn} and \texttt{outcome} instead. We will test your AGS on games that are quite different from Tic-Tac-Toe.

To test your AGS, you'll need to replace our \texttt{ags.ui} and \texttt{ags.wo} files with the ones you compile from your source code. At this point you'll be able to run the same test cases you used earlier, as well as what's in \texttt{part B}.

The course solution AGS takes about 40 lines of Standard ML.

\textbf{A common mistake to avoid when debugging your AGS}

If you build a simple AGS that fits in 40 lines of code, it is not going to try to fool you: if you can force a win, the AGS will pick a move more or less arbitrarily. A simple AGS has no notion of "better" or "worse" moves; it knows only whether it can force a win.

Here's the common mistake: you're playing against the AGS, and it makes a terrible move. You think it's broken. For example, suppose you are playing X, the AGS is playing O, and you start play in this position:

\begin{center}
\begin{tabular}{|c|c|c|}
\hline
 & O & \\
\hline
 & | & \\
\hline
 X & | & \\
\hline
 & | & \\
\hline
\end{tabular}
\end{center}

You move in the upper left corner. The AGS does not move lower right to block you. Is it broken? No—the AGS recognizes that you can force a win, and it just gives up.

If you want an AGS that won't give up, for extra credit you can implement an aggressive version that will delay the inevitable as long as possible. An aggressive AGS searches more states so that it can (a) win as quickly as possible and (b) hold on in a lost position as long as possible.

The aggressive course solution for AGS is under 60 lines of Standard ML code.

\textbf{Using your AGS to play other games}

The code we supply includes a description of the game "Nim". The structure that implements "Nim" is called \texttt{structure Nim}. After you create an AGS solver and an interactive player for "Nim" you can play Nim with the AGS. The commands to instantiate AGS to "Nim" are:

\begin{verbatim}
<nim examples>
 structure NIMAgs = AgsFun(structure Game = Nim) structure PN = PlayFun(structure Ags = NIMAgs)
\end{verbatim}

You play Nim by running \texttt{/comp/105/bin/nim}, but the user interface stinks.

We've also implemented a version of "Connect 4" that would be better called "Connect 3" (since 4 would be too slow). It is in \texttt{/comp/105/bin/four}.
Descriptions of the games

Here are descriptions of 3 games: "Tic-Tac-Toe", "Nim" and "Connect 4". Do not worry if you haven't seen these games before—you can learn by playing against a perfect or near-perfect player. (The Connect 4 player would be perfect if it were faster.) For the purpose of this assignment you do not have to know any tricks of the games but only to understand their rules.

**Tic Tac Toe**

This is an adversary game played by two persons using a 3x3 square board. The players (traditionally called X and O) take turns in placing X's or O's in the empty squares on the board (player X places only X's and O only O's). The board is empty in the initial configuration.

The first player who managed to obtain a full line, column or diagonal marked with his name is the winner. The game can also end in a tie. In the picture below the first configuration is a win for O, the next two are wins for X and the last one is a tie.

```
-------------    -------------    -------------    -------------
| X |   | X |    |   |   | X |    | X | O |   |    | O | O | X |
-------------    -------------    -------------    -------------
|   | X |   |    | O | X | O |    | X | O |   |    | X | X | O |

-------------    -------------    -------------    -------------
```

In this game a player who plays perfectly cannot lose. All your base are belong to the AGS.

**Nim**

This is an adversary game played by two persons. The game is played with number of sticks arranged in 3 rows. In the initial state the rows usually contain 3, 5 and 7 sticks respectively. The players take turns in removing sticks: each player can remove 1, 2 or 3 adjacent sticks from one row. The one that removes the last stick is the loser. Or, stated differently the first player who has no sticks to remove is the winner. Below are two configurations. The first one is the initial configuration (for the 3, 5 and 7) case and the other one is the configuration obtained after a few moves. A possible sequence of moves that might lead to this configuration is:

1. X removes sticks 0, 1 and 2 from row 1
2. O removes stick 1 from row 0
3. X removes stick 6 from row 2
4. O removes sticks 3 and 4 from row 2

```
Row 0: | | |   | _ |
Row 1: | | | |   _ _ _ | _ |
Row 2: | | | | |   | _ _ | _ _ |
```

We have represented a stick using a "|" and a missing stick using a "_". It might be wise to play with a smaller configuration (2, 3 and 4 for example) because otherwise the AGS will take too long to produce its answers.

For this game the first player can always win no matter what the other does. If you let the AGS start you have no chance. If you play first you can beat the AGS, but you have to play well.

**Connect 4**

This is an adversary game played by two persons using 6 rods and 36 balls. Imagine the rods standing vertically, and each ball has a hole in it, so you can drop a ball onto a rod. The balls are divided in two equal groups marked X and O. The players take turns in making moves. A move for a player consists in sliding one of its own balls down a rod which is not full (the capacity of a rod is 6). The purpose is to obtain 4 balls of the same type adjacent on a horizontal, vertical or diagonal line.
The game ends in a tie when all the rods are full and no player has won. We represent below the initial configuration of the game and a final state where X has won.

```

```

Our version uses 5 rods and connects 3, because otherwise the AGS takes too long.

**Extra Credit**

**Proof.** Prove the "forcing" property of these simple games as described above above.

**Four.** Implement Connect 4.

**Aggression.** With the simple benefits outlined above, the AGS will "give up" if it can't beat a perfect player---all moves are equally bad, and it apparently moves at random. What this scheme doesn't account for is that the other player might not be perfect, so there is a reason to prefer the most distant loss. In the dual situation, when the AGS knows it can win no matter what, it will pick a winning move at random instead of winning as quickly as possible. *This behavior may lead you to suspect bugs in your AGS. Don't be fooled.*

Change your benefits so that the AGS prefers the closest win and the most distant loss. (This means you can only prune the search if you find a win in one move.) If you are clever, you can encode all this information in one value of type `real`.

**What to submit**

You should submit the following files (at least five):

- A `README` file containing
  - the names of the people with whom you collaborated
  - the numbers of the problems that you solved (including any extra credit)
  - the number of hours you worked on the assignment.
- `heap-sig.sml` and `heapsort.sml`, implementing your solution to Problem 1
- `ttt.sml`, implementing your solution to Problem A
- `ags.sml`, implementing your solution to Problem B
- For problems A and B, your `compile` and `ttt.mlb` files. (See Appendix 1 for information on the these files.)
- For problems A and B, any other files you need in order to compile `ttt.sml` and `ags.sml`.

The ML files that you submit should contain all structure and function definitions that you write for this assignment (including any helper functions that may be necessary), in the order they should be compiled. The files you submit must compile with Moscow ML, using the `compile` script we give you. We will reject files with syntax or type errors. Your files should compile *without warning messages*. If you must, you can include multiple structures in your files, but *please don't make copies of the structures and signatures above*; we already have them.

**How to submit**

When you are ready, run `submit105-sml` to submit your work. Note you can run this script multiple times; we will grade the last submission.
Acknowledgments

This assignment is derived from one graciously provided by Bob Harper. George Necula, who was his teaching assistant at the time (and is now a professor at Berkeley and is world famous as the inventor of proof-carrying code), did the bulk of the work.

Appendix I: Two ways to compile Standard ML modules

Compiling Standard ML modules using Moscow ML

To compile an individual module using Moscow ML, you type

```
mosmlc -c -toplevel filename.sml
```

This puts compiler-interface information into `filename.ui` and implementation information into `filename.uo`. Perhaps surprisingly, either a signature or a structure will produce both `.ui` and `.uo` files. This behavior is an artifact of the way Moscow ML works; it should not alarm you.

If your module depends on another module, you will have to mention the `.ui` file on the command line as you compile. For example a `DictFn` functor depends on both `DICT` and `KEY` signatures. If `DictFn` is defined in `dict.sml`, `KEY` is defined in `key-sig.sml`, and `DICT` is defined in `dict-sig.sml`, then to compile `DictFn` you run

```
mosmlc -toplevel -c dict-sig.ui key-sig.ui dict.sml
```

To talk about what happens after you compile, I'll use another example:

```
mosmlc -c -toplevel game-sig.ui player.ui ttt.sml
```

This compilation produces two files:

- `ttt.ui`, which can be used on the command line when compiling other units that depend on TTT.
- `ttt.uo`, which contains the compiled binary

You can do two things with the `.uo` files:

- **When you are debugging**, it is tremendously useful to get compiled modules into the interactive system. Load them directly using `load`, e.g.,

  ```
  prompt>  mosml
  Moscow ML version 2.10-3 (Tufts University, April 2012)
  Enter `quit();' to quit.
  - load "ttt";
  > val it = () : unit
  - open TTT;
  > structure Move :
  (type move = move,
   exn Move = Move : exn,
   ...
  type config = config
  ...
  val finished = fn : config -> bool
  ...
  ```

  **Once you load a module, you cannot recompile it and reload it later.** Loading it again has no effect, even if the code has changed; you have to start Moscow ML over again.

- **You can use mosmlc to link a bunch of .uo files together to form an executable binary.** To do anything interesting,
one of the source files should have a top-level call to `play`, `forecast`, or some other interesting function.

Here is an example of a command line I use on my system to build an interactive game player:

```
mosmlc -toplevel -o games player-sig.uo player.uo game-sig.uo \
  ags-sig.uo play-sig.uo slickttt.uo ttt.uo \
  ags.uo aggress.uo nim.uo four.uo peg.uo mrun.uo
```

Order matters; for example, I have to put `player.uo` after `player-sig.uo` because the `Player` structure defined in `player.sml` uses the `PLAYER` signature defined in `player-sig.sml`.

The git repository for this assignment includes a compile script that may help with compiling Moscow ML modules.

**Compiling Standard ML to native machine code using MLton**

If your games are running too slow, compile them with MLton. MLton is a whole-program compiler that produces optimized native code. To use MLton, you list all your modules in an MLB file, and MLton compiles them at one go. We provide a `ttt.mlb` file, so you can compile with, e.g.,

```
mlton -output ttt -verbose 1 ttt.mlb
```

Because MLton requires source code, you will be able to use it only once you have your own AGS. More information about MLton is available on the man page and at [www.mlton.org](http://www.mlton.org).

**Appendix II: The code we give you and how to get it**

In the git repository at `/comp/105/git/ttt`, you'll find sources for most of the signatures, structures, and functors in this assignment. You'll also find an AGS in binary form only. And you'll find a compile script, which should compile your code using the Moscow ML compiler, mosmlc, and a `ttt.mlb` file for MLton.

**Appendix III: How your work will be evaluated**

**Interface design and modular programming**

Modules provide controlled information hiding. To use the power of modules effectively, design interfaces that are both usable and abstract:

- Enough types should be made manifest that the module can be used.
- No more types should be made manifest than is absolutely necessary.

Here's an acid test:

- If an interface exports an abstract type like `heap` or `queue` or `dictionary` or `computation`, it must be possible to create a value of the abstract type using the functions exported by the interface. It must not be possible to create a value of the abstract type without using the functions exported by the interface.

Other things being equal, hiding more information is better. When in doubt, make a type abstract.

**Mutability**

An abstract type, in any language, is always either mutable or immutable. The choice is made by the designer of the interface, and the choice is available regardless of programming language.
Mutable abstractions have “object identity”: if you mutate \( x \) and you see the change when you look at \( y \), then \( x \) and \( y \) are the same object. For example, if sets of numbers are mutable abstractions, then just because \( x \) and \( y \) both represent the empty set doesn't mean they are the same object.

Immutable abstractions lack object identity: if the result of observing a property of \( x \) is always identical to the result of observing the same property of \( y \), then they may or may not be the same object, but it doesn't matter, because no program can tell the difference between them. For example, “natural number” is an immutable abstraction, and if you have the natural number 7, it makes no sense to ask “which 7 do I have,” because they're all indistinguishable.

The interface for a mutable abstraction always provides at least one creator function which creates a new object that is distinct from any other. The interface for an immutable abstraction doesn't require creators. For example, if you implement mutable lists, you need a way to allocate a new, empty list. But if lists are immutable, you can just provide one empty-list value and forget about it.

The interface for a mutable abstraction provides mutators that change the contents or value of an object. The return type of a mutator typically does not include a value of the abstract type; instead of a returning a new value, the mutator changes one of its arguments. The interface for an immutable abstraction typically provides producers that take in an existing object and produce a new object, which is returned. The return type of a producer always includes a value of the abstract type.

In a statically typed language like ML, it is usually not necessary to say explicitly whether an abstraction is mutable or immutable—it should be obvious from the types.

The key takeaway here is that any abstraction you create should be either mutable or immutable, and the type of every operation must be consistent with your decision.

**Evaluation criteria**

**Interface design and documentation**

We'll look most closely at the design and documentation of your interfaces.

<td>• Code is somewhat larger than necessary to solve the problem.</td>
<td>• Code has more than one redundant case analysis</td>
</tr>
</tbody>
</table>

| Performance and correctness |

Finally, we'll look to be sure your code meets specifications, and that the performance of your AGS is as good as reasonably possible.

<table>
<thead>
<tr>
<th>Exemplary</th>
<th>Satisfactory</th>
<th>Must improve</th>
</tr>
</thead>
<tbody>
<tr>
<td>Correctness</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• The <strong>HEAP</strong> signature contains only operations that are appropriate to a set with a known minimum element.</td>
<td>• The <strong>HEAP</strong> signature contains superfluous operations.</td>
<td>• The <strong>HEAP</strong> signature contains superfluous operations that the course staff believe are intended to make sorting easier.</td>
</tr>
<tr>
<td>• The <strong>HEAP</strong> signature exposes the total order that exists on values of the element type.</td>
<td>• Tic-tac-toe code fulfills the contracts specified in the <strong>GAME</strong> and <strong>MOVE</strong> signatures, except that it continues to offer moves even after the game is over.</td>
<td>• The <strong>HEAP</strong> signature contains a sort function (<strong>serious fault</strong>).</td>
</tr>
<tr>
<td>• Tic-tac-toe code fulfills the contracts specified in the <strong>GAME</strong> and <strong>MOVE</strong> signatures.</td>
<td>• AGS code makes no additional assumptions about the implementations of <strong>Player</strong>, <strong>Move</strong>, or <strong>Game</strong>.</td>
<td>• The <strong>HEAP</strong> signature contains a higher-order function that visits</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
heap elements in total order (serious fault).

- The HEAP signature does not expose the total order that exists on values of the element type.
- Tic-tac-toe code violates one of its contracts.
- AGS code assumes that players take turns.

Performance

- The AGS implements its bestmove and forecast functions using a single, pruned search that stops once the best move or outcome is known.
- Or, the AGS implements bestmove and forecast by making just one search through the state space of possible game configurations.
- Function bestmove or forecast may search the state space of possible configurations more than once.
- Function bestmove or forecast may search the state space of possible configurations more than twice.
