

LP in 2-D

$$\min_{x_1, x_2} c_1 x_1 + c_2 x_2$$

$$\Rightarrow a_{i,1} x_1 + a_{i,2} x_2 \geq b_i \quad i=1, \dots, n.$$

$$\min_{x, y} y$$

$$\Rightarrow y \geq a_i x + b_i \quad i \in I_1$$

$$y \leq a_i x + b_i \quad i \in I_2$$

$$a \leq x \leq b$$

$$|I_1| + |I_2| \leq n$$

$$-\infty \leq a, b \leq \infty$$

$$\min g(x)$$

$$\Rightarrow g(x) \leq h(x)$$

$$a \leq x \leq b$$

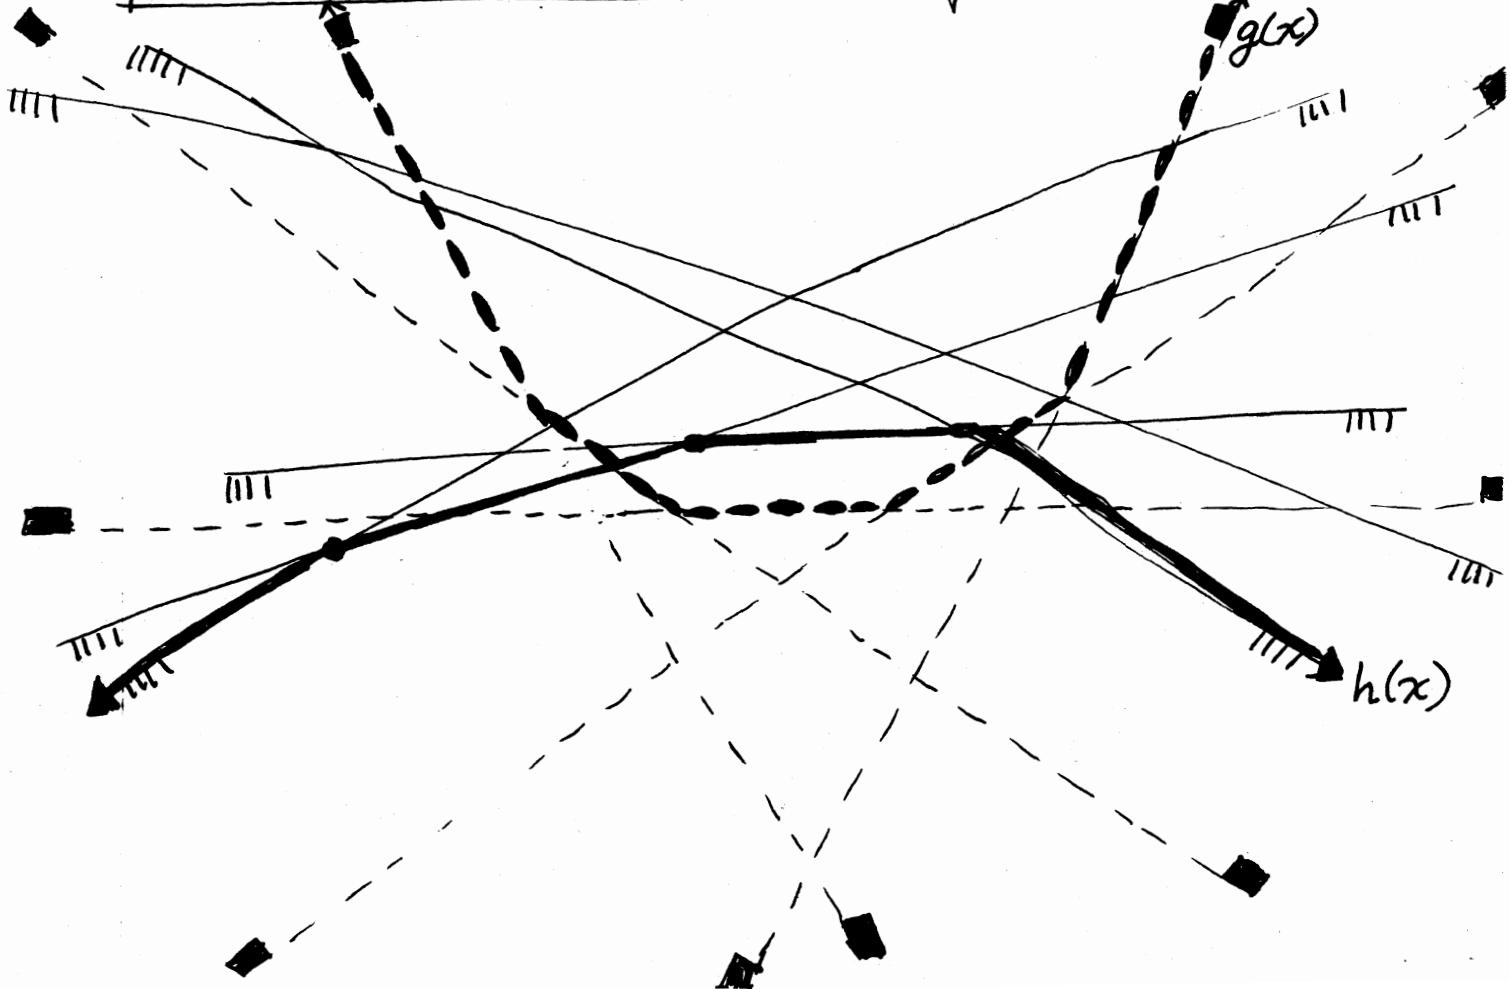

Define:

$$g(x) = \max \{a_i x + b_i : i \in I\}$$

$$h(x) = \min \{a_i x + b_i : i \in I\}$$

Piecewise linear.

$$g(x)$$

A given value x' of x , $a \leq x' \leq b$, is feasible iff $g(x') \leq h(x')$. If x' is not feasible, any feasible values must lie to one side of x' . If x' is feasible, we test whether x' is optimal and, if not, determine on which side the minimum lies. Let x^* denote optimal solution.

Define $f(x) = g(x) - h(x)$ [For feasible x , $f(x) \leq 0$]

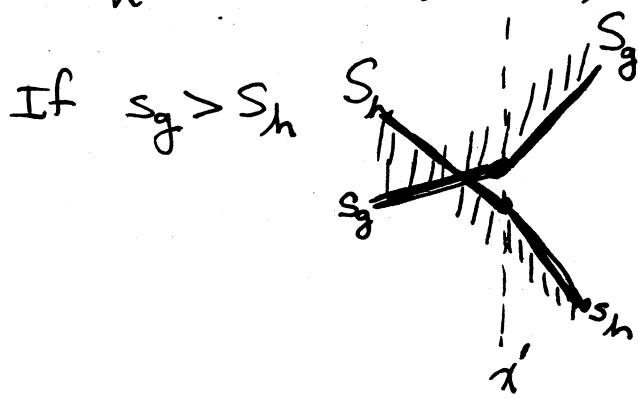

INFEASIBLE x' : $f(x') > 0$ and $g(x') > h(x')$.

$$s_g(x') = \min\{a_i : i \in I_1, a_i x' + b_i = g(x')\}$$

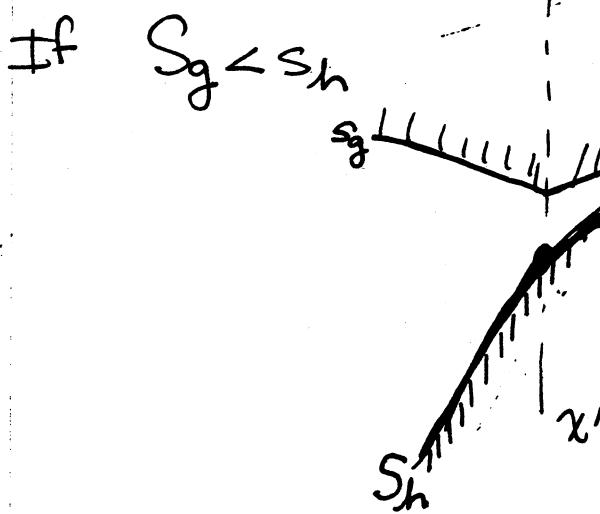

$$s_h(x') = \max\{a_i : i \in I_1, a_i x' + b_i = h(x')\}$$

$$s_g(x') = \min\{a_i : i \in I_2, a_i x' + b_i = g(x')\}$$

$$s_h(x') = \max\{a_i : i \in I_2, a_i x' + b_i = h(x')\}$$

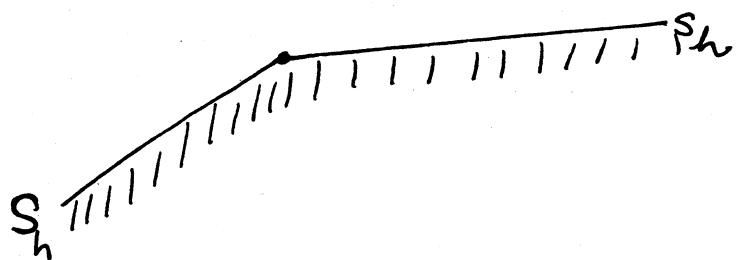

all feasible x are smaller than x'
So $x^* < x'$, if $\exists x^*$

all feasible x are larger than x'
So $x^* > x'$, if $\exists x^*$

If $s_g - S_h \leq 0 \leq S_g - s_h$

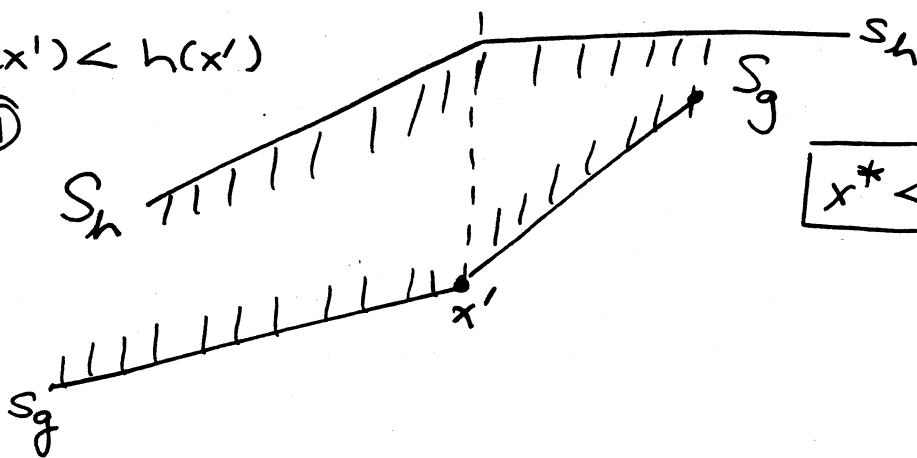

NO FEASIBLE X

FEASIBLE X': $f(x') \leq 0$ and $g(x') \leq h(x')$

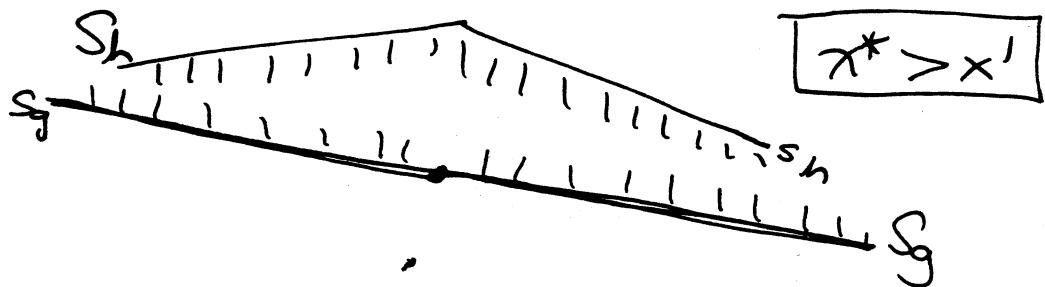

If $g(x') < h(x')$

①

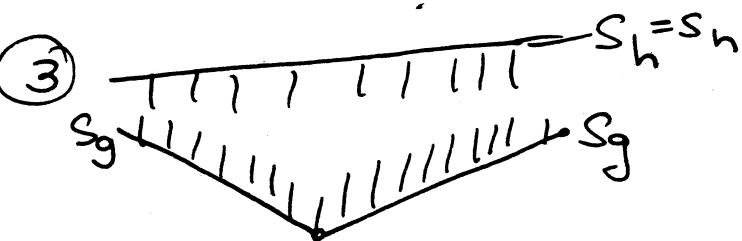

$$x^* < x'$$

②

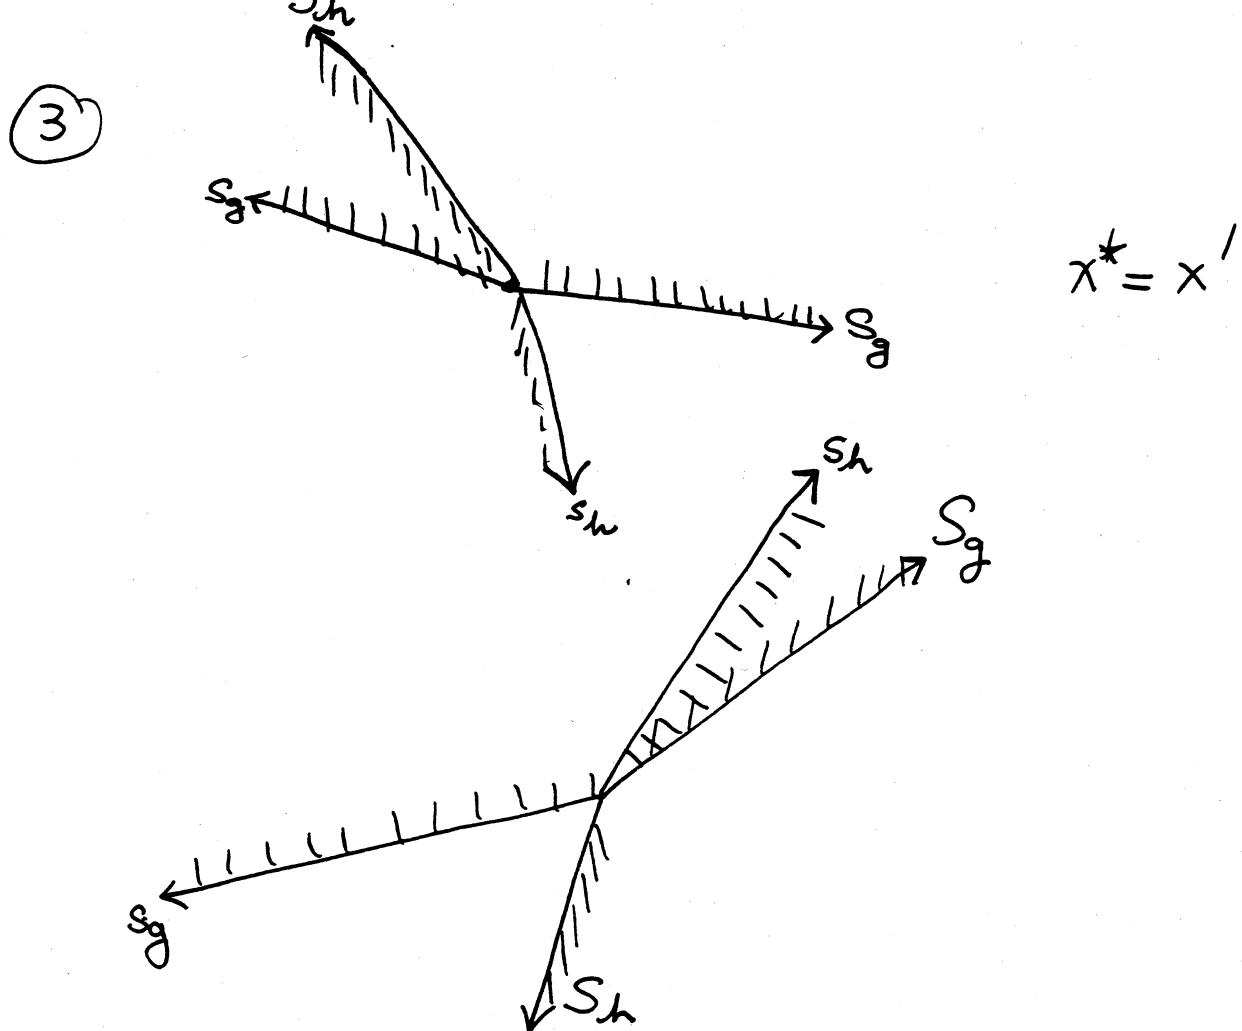

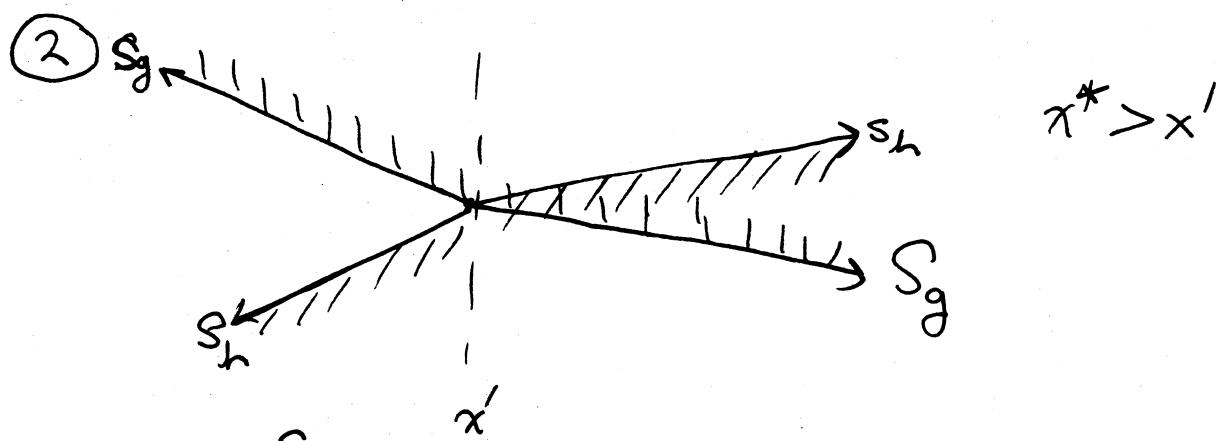

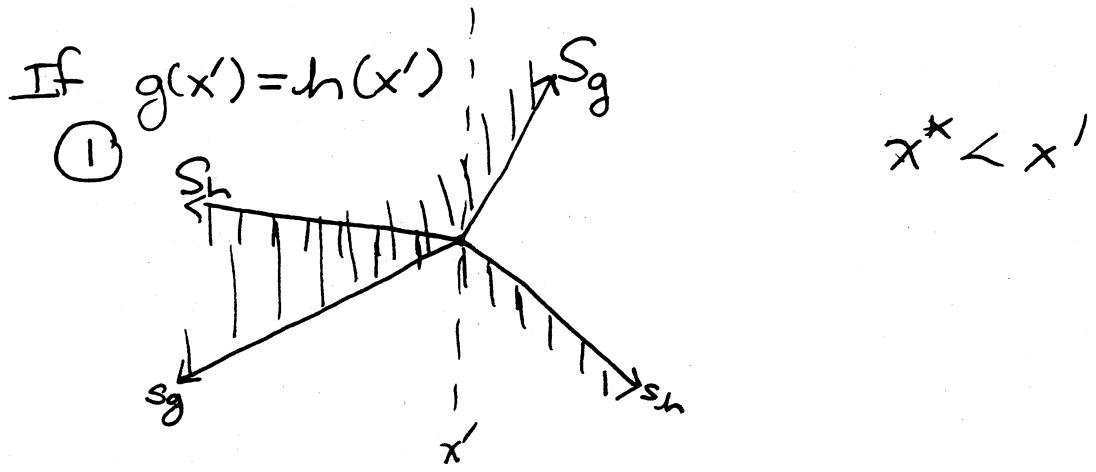

$$x^* > x'$$

③

$$\begin{aligned} s_g &\leq 0 \leq S_g \\ x^* &= x' \end{aligned}$$

2D LP continued

If $x' \in [a, b]$, then $O(n)$ time decides whether

@ problem infeasible

(b) $x^* = x'$

(c) $x^* \in [a, x']$ if $\exists x^*$

(d) $x^* \in [x', b]$ if $\exists x^*$

Remember: PROBLEM CAN BE
UNBOUNDED.

So, how shall we choose which value of x' to test?

Arrange elements of I_1 (resp I_2) in disjoint pairs

Either ① If $a_i = a_j$ in pair (i, j) , drop redundant line

OR ② Compute $x_{ij} = \frac{b_i - b_j}{a_j - a_i}$, the intersection pt.
Assume $a_j > a_i$

If $x^* \in [a, x_{ij}]$ and $i, j \in I_1$, then line j is red.

If $x^* \in [x_{ij}, b]$ and $i, j \in I_1$, then line i is red.

If $x^* \in [a, x_{ij}]$, $i, j \in I_2$, line i is redundant

If $x^* \in [x_{ij}, b]$, $i, j \in I_2$, line j is redundant

Algorithm

Find median value of x_{ij} , x_m

Choose appropriate interval $[a, x_m]$ or $[x_m, b]$

That interval contains at most half of the x_{ij} .

For each of the remaining x_{ij} 's, one constraint can be removed.

$$T(n) \leq Cn + T\left(\frac{3n}{4}\right) = O(n).$$

LP in \mathbb{R}^3

$$\min_{x_1, x_2, x_3} \gamma_1 x_1 + \gamma_2 x_2 + \gamma_3 x_3 \quad \exists a_{i1} x_1 + a_{i2} x_2 + a_{i3} x_3 \geq \beta_i \quad i=1, \dots, n$$

\Downarrow Transformation of coordinates

$\min_z z$ such that

$$z \geq a_i x + b_i y + c_i \quad i \in I_1$$

$$z \leq a_i x + b_i y + c_i \quad i \in I_2$$

$$a_i x + b_i y + c_i \leq 0 \quad i \in I_3$$

$$|I_1| + |I_2| + |I_3| = n$$

DEFINE

$\min_{x,y} g(x,y)$ such that
 $f(x,y) \leq 0$

$$g(x,y) = \max_{i \in I_1} \{a_i x + b_i y + c_i\}$$

$$h(x,y) = \min_{i \in I_2} \{a_i x + b_i y + c_i\}$$

$$e(x,y) = \max_{i \in I_3} \{a_i x + b_i y + c_i\}$$

$$f(x,y) = \max \{g(x,y) - h(x,y), e(x,y)\}$$

NOTE 1) $e(x,y)=0$ defines a convex polygon in the $x-y$ plane which delimits the domain of the LP problem

2) for a point (x,y) in the domain to be feasible, then $g(x,y) \leq h(x,y)$, so:

$(x,y) \in \mathbb{R}^2$ is feasible iff $f(x,y) \leq 0$.

GOAL: Test a straight line in \mathbb{R}^2 and restrict further search to one half-plane or the other, or else stop.

PROCEDURE: W.L.O.G, assume line is x-axis (^{transform} coordinates).

Determine @ problem infeasible; ⑥ global minimum has $y=0$;
⑦ problem is unbounded; ⑧ search $\{(x,y) : y \geq 0\}$; ⑨ search $\{(x,y) : y < 0\}$ by first solving the 2D LP $\min(g(x,p)) \geq f(x,0) \leq 0$.

Either ⑩ problem unbounded \Rightarrow 3D problem unbounded
or ⑪ problem infeasible, with $(x^*, 0)$ the min of $f(x, 0)$.
or ⑫ $(x^*, 0)$ min of $g(x, 0)$ for $f(x, 0) \leq 0$.

If a), we are done

Assume $(x^*, 0)$ is reported and WLOG assume $x^* = 0$.

Further steps from here rely only on constraints which are tight at $(0, 0)$. We isolate those constraints

DEFINE $I_j^* \subset I_j$, $j \in \{1, 2, 3\}$

$i \in I_1 \Rightarrow i \in I_1^*$ if ~~$c_i \cdot c_i = g(0, 0)$~~

$i \in I_2 \Rightarrow i \in I_2^*$ if $c_i = h(0, 0)$ AND $f(0, 0) = g(0, 0) - h(0, 0) \geq 0$

$i \in I_3 \Rightarrow i \in I_3^*$ if $c_i = e(0, 0)$ AND $f(0, 0) = e(0, 0) \geq 0$

Using only those constraints which are tight at $(0, 0)$, we can search locally at $(0, 0)$ and decide in which half-space an optimal solution may lie. But we shall consider then a very small neighborhood of $(0, 0)$ so as to be sure not to violate any other constraints.

We divide the procedure from here into two halves:

~~1st~~ first we assume $f(0, 0) \leq 0$, i.e. $x^* = 0$ is feasible.
second we assume $f(0, 0) > 0$, i.e. $x^* = 0$ is infeasible

CASE I : $f(0,0) \leq 0$, so $x^* = 0$ IS A FEASIBLE POINT

Prop 1 $\exists (x,y)$ with $y > 0$, $g(x,y) < g(0,0)$ and $f(x,y) \leq 0$

IFF $\exists \lambda$ such that

$$\textcircled{1} \max_{i \in I_1^*} \{a_i \lambda + b_i\} \leq 0$$

AND

$$\textcircled{2} \max_{i \in I_1^*} \{a_i \lambda + b_i\} \leq \min_{i \in I_2^*} \{a_i \lambda + b_i\}$$

AND

$$\textcircled{3} \max_{i \in I_3^*} \{a_i \lambda + b_i\} \leq 0$$

PROP 2 ... ~~$y < 0$~~ ... IFF

$$\textcircled{1} \min_{i \in I_1^*} \{a_i \lambda + b_i\} > 0$$

$$\textcircled{2} \min_{i \in I_1^*} \{a_i \lambda + b_i\} \geq \max_{i \in I_2^*} \{a_i \lambda + b_i\}$$

$$\textcircled{3} \min_{i \in I_3^*} \{a_i \lambda + b_i\} \geq 0$$

Proof of Prop 1

\Rightarrow Assume such an (x,y) . Let $\lambda = \frac{x}{y}$. Recall that $y > 0$.

$$\textcircled{1} \max_{i \in I_1^*} \{a_i \lambda + b_i\} + c_i \leq g(\lambda y, y) \leq g(0,0) = \max_{i \in I_1^*} \{c_i\}$$

$$\text{So } \max_{i \in I_1^*} \{a_i \lambda + b_i\} \leq 0$$

$\textcircled{2}$ If $I_2^* = \emptyset$, trivial. Assume $I_2^* \neq \emptyset$. Then $f(0,0) = g(0,0) - h(0,0) = 0$

Therefore $\forall i \in I_1^*, \forall j \in I_2^*, c_i = c_j = q$

$$\max_{i \in I_1^*} \{a_i \lambda y + b_i y + c_i\} \leq g(\lambda y, y) \leq h(\lambda y, y) \leq \min_{i \in I_2^*} \{a_i \lambda y + b_i y + c_i\}$$

Subtracting $c_i = q$ and dividing by $y > 0$ yields

$$\max_{i \in I_1^*} \{a_i \lambda + b_i\} \leq \min_{i \in I_2^*} \{a_i \lambda + b_i\}$$

$\textcircled{3}$ If $I_3^* = \emptyset$, trivial. Assume $I_3^* \neq \emptyset$. Then $f(0,0) = e(0,0) = c_j \geq 0$

for all $j \in I_3^*$. But $f(0,0) \leq 0$ by the premise. So $c_j = 0$.

$$\text{AND } c_j = \max_{i \in I_3^*} \{c_i\}.$$

$$\text{So } \max_{i \in I_3^*} \{a_i \lambda y + b_i y + c_i\} \leq 0 \text{ and}$$

$$\max_{i \in I_3^*} \{a_i \lambda + b_i\} \leq 0$$

Proof of Prop 1 \Leftarrow Assume $\exists \gamma$ which satisfies 1, 2, 3.

If $y > 0$ is sufficiently small, then the constraints in I_1^* , I_2^* , and I_3^* are still the only ones which apply.

So $g(\lambda y, y) < g(0, 0)$ since

$$\max_{i \in I_1^*} \{a_i \lambda y + b_i y + c_i\} \leq \max_{i \in I_1^*} \{a_i \lambda + b_i\} y + \max_{i \in I_1^*} \{c_i\}$$

$$\leq 0y + g(0, 0) \leq g(0, 0)$$

Furthermore $f(\lambda y, y) \leq 0$ since $\forall i \in I_1^*, \forall j \in I_2^*, c_i = c_j$ and $\max_{i \in I_1^*} \{a_i \lambda + b_i\} y + \max_{i \in I_1^*} \{c_i\} \leq \min_{i \in I_2^*} \{a_i \lambda + b_i\} y + \max_{i \in I_2^*} \{c_i\}$

The Test Given $I_j^*, j = 1, 2, 3$

First solve $\min_{\lambda, n} n$

$$n \geq a_i \lambda + b_i \quad i \in I_1^*$$

$$n \leq a_i \lambda + b_i \quad i \in I_2^*$$

$$a_i \lambda + b_i \leq 0 \quad i \in I_3^*$$

Second solve $\min_{\lambda, n} n$

$$n \leq a_i \lambda + b_i \quad i \in I_1^*$$

$$n \geq a_i \lambda + b_i \quad i \in I_2^*$$

$$a_i \lambda + b_i \geq 0 \quad i \in I_3^*$$

If $n < 0$, choose $y > 0$

If $n > 0$, choose $y < 0$

ELSE Keep $y=0$, so $(0, 0)$ is optimal.

CASE II: $f(0,0) > 0$ (INFEASIBLE POINT)

Prop3 $\exists(x,y)$ with $y > 0$, $f(x,y) < f(0,0)$ IFF $\exists \lambda$ such that

① $\max_{i \in I_1^*} \{a_i \lambda + b_i\} < \min_{i \in I_2^*} \{a_i \lambda + b_i\}$ AND Prop 4 ... $y < 0 \dots$

② $\max_{i \in I_3^*} \{a_i \lambda + b_i\} < 0$

① $\min_{i \in I_1^*} \{a_i \lambda + b_i\} > \max_{i \in I_2^*} \{a_i \lambda + b_i\}$ AND

② $\min_{i \in I_3^*} \{a_i \lambda + b_i\} > 0$

The TEST

First $\min_{\lambda} \varphi(\lambda)$ where $\varphi(\lambda)$ represents the convex, piecewise linear

$$\varphi(\lambda) = \max \left\{ \max_{i \in I_1^*} \{a_i \lambda + b_i\} - \min_{i \in I_2^*} \{a_i \lambda + b_i\}, \max_{i \in I_3^*} \{a_i \lambda + b_i\} \right\}$$

[Use 2D LP where you pair indices only if $i, j \in I_k^*$ for the same $k \in \{1, 2, 3\}$]

If $\varphi < 0$, then choose $y > 0$.

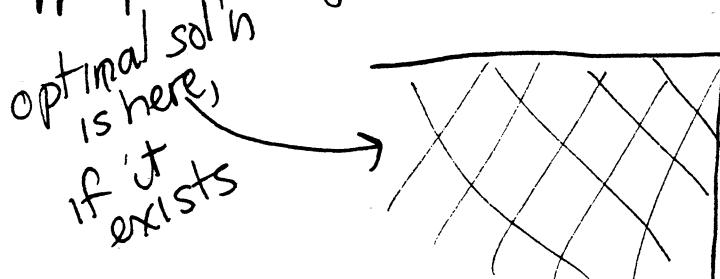

Second $\max_{\lambda} \varphi(\lambda) = \min \left\{ \min_{i \in I_1^*} \{a_i \lambda + b_i\} - \max_{i \in I_2^*} \{a_i \lambda + b_i\}, \min_{i \in I_3^*} \{a_i \lambda + b_i\} \right\}$

If $\varphi > 0$, then choose $y < 0$.

ELSE f attains its global minimum on the x -axis
 \Rightarrow problem is infeasible.

THE ALGORITHM

- ① Pair the constraints in I_1 , I_2 , and I_3 individually.
In each pair (i, j) , either discard one parallel constraint or compute the intersection line L_{ij} in the xy -plane. That line divides the xy -plane into 2 half-planes:
In one, constraint i is redundant; in the other, j is.
- ② Once you have computed all the lines L_{ijk} for each disjoint pair $(i, j, k) \in J_K$, transform coordinates so that half the lines have positive slope and half have negative slope.
- ③ Pair one line L_{ij} with positive slope with one line L_{kh} of negative slope and compute the intersection point P_{ijkh} . The xy -plane is divided into four sectors each of which is associated with just two constraints:
- ④ Choose the median y -coordinate of all the P_{ijkh} . Test that line + choose the appropriate half-plane.
- ⑤ Choose the median x -coordinate of the P_{ijkh} NOT belonging to that half plane. ~~Test that line~~
Test that line and choose the appropriate quadrant

$C_i \& C_k \rightarrow L_{ij}$

$C_j \& C_k \rightarrow L_{kh}$

$C_i \& C_h \rightarrow L_{kh}$

$\frac{1}{4}$ of the P_{ijkh} lie here.
Constraint C_k is redundant.

⑥ At least $\frac{1}{4}$ of the P_{ijkh} lie in the diagonally opposing quadrant. Since one of L_{ij} has ~~one~~^{and L_{kh}} positive slope and one has negative slope, one of these lines never enters the chosen quadrant. Therefore one constraint is redundant. So $\frac{1}{16}$ of the constraints, at least, are eliminated.

$$LP(3, n) \leq Cn + \cancel{2LP(2, n)} + LP\left(3, \frac{15n}{16}\right)$$

$$= O(n)$$
