# Introduction to Matroids 

Guest lecture in COMP150-Graph Theory<br>Anselm Blumer 31 October, 2019

## What is a matroid?

- A mathematical structure that generalizes concepts from graph theory, linear algebra, etc.
- Introduced in the 1930s by Whitney, Nakasawa, MacLane, and van der Warden
- Based on the concept of hereditary system
- This lecture assumes matroids are finite to avoid problems with duality, though recent work by Bruhn, Diestel, Kriesell, Pendavingh, and Wollan (2013), has extended the theory to infinite objects called $B$-matroids

## So what is a hereditary system?

- A hereditary system, M, on a set, E (the ground set), consists of a nonempty collection, $\mathrm{I}_{\mathrm{M}}$, of subsets of E with the property that every member of $\mathrm{I}_{\mathrm{M}}$ also has all its subsets in $\mathrm{I}_{\mathrm{M}}$.
- Hereditary systems are also called independence systems or abstract simplicial complexes
- The members of $\mathrm{I}_{\mathrm{M}}$ are called independent sets.
- There may be several ways of specifying $\mathrm{I}_{\mathrm{M}}$. These are called aspects of M.

## An example of a hereditary system and independent sets

- $\mathrm{E}=$ edges of the kite

- $\mathrm{I}_{\mathrm{M}}=$ sets of edges with no cycle
- every set with more than three edges is dependent
- two more dependent sets = ??
- maximal independent sets = spanning trees

## Some more terminology for independent sets

- $\mathrm{B}_{\mathrm{M}}=$ bases $=$ maximal independent sets
- $\mathrm{C}_{\mathrm{M}}=$ circuits $=$ minimal dependent sets
- $\mathrm{r}_{\mathrm{M}}(\mathrm{X}$ a subset of E$)=$ rank $=$ maximum size of an independent set $=\max \left\{|\mathrm{Y}|: \mathrm{Y} \subseteq \mathrm{X}, \mathrm{Y} \in \mathrm{I}_{\mathrm{M}}\right\}$
- $r_{M}()$ satisfies the following two properties (Lemma 8.2.17):
(r1) The rank of the empty set is zero
(r2) If $X \subseteq E$ and $e \in E$, then $r_{M}(X) \leq r_{M}(X+e) \leq r_{M}(X)+1$

## Another example of a hereditary system

- $\mathrm{I}_{\mathrm{M}}=$ sets of edges with no cycle
- dependent sets = ??

- $\mathrm{C}_{\mathrm{M}}=$ circuits $=$ ??
- $\mathrm{B}_{\mathrm{M}}=$ bases $=$ ??
- $\mathrm{r}_{\mathrm{M}}()=\operatorname{rank}=$ ? ?

## Another example of a hereditary system

- $\mathrm{I}_{\mathrm{M}}=$ sets of edges with no cycle
- dependent sets $=\{1,2\}$ and $\{1,2,3\}$

- $\mathrm{C}_{\mathrm{M}}=$ circuits $=\{1,2\}$
- $\mathrm{B}_{\mathrm{M}}=$ bases $=\{1,3\}$ and $\{2,3\}$
- $\mathrm{r}_{\mathrm{M}}()=\operatorname{rank}=\operatorname{size}($ if independent $)$

$$
r(\{1,2\})=1 \quad r(\{1,2,3\})=2
$$

## A matroid is a hereditary system with an additional property

- One such property is the base exchange property:
- if $\mathrm{B}_{1}$ and $\mathrm{B}_{2}$ are bases, then for every $e$ in $\mathrm{B}_{1}-\mathrm{B}_{2}$ there is an $f$ in $\mathrm{B}_{2}-\mathrm{B}_{1}$ so that $\mathrm{B}_{1}-\{e\}+\{f\}$ is a base
- For example, in a connected graph the bases are spanning trees Deleting an edge from a spanning tree disconnects it The two components can be reconnected using a different edge from another spanning tree
- One consequence is that all bases have the same size, which you already know to be true of spanning trees (or spanning forests in the case of graphs with more than one component)

## A matroid is a hereditary system with an additional property

- Another such property is the (weak) absorption property:
- if X is a subset of E and $f$ and $g$ are members of E with $\mathrm{r}(\mathrm{X})=\mathrm{r}(\mathrm{X}+e)=\mathrm{r}(\mathrm{X}+f)$, then $\mathrm{r}(\mathrm{X})=\mathrm{r}(\mathrm{X}+e+f)$

## A matroid is a hereditary system with an additional property

- Another such property is the (weak) absorption property :
- if X is a subset of E and $f$ and $g$ are members of E with

$$
\begin{aligned}
& \mathrm{r}(\mathrm{X})=\mathrm{r}(\mathrm{X}+e)=\mathrm{r}(\mathrm{X}+f) \text {, then } \\
& \mathrm{r}(\mathrm{X})=\mathrm{r}(\mathrm{X}+e+f)
\end{aligned}
$$

- There must be a strong absorption property :
- if X and Y are subsets of E with $\mathrm{r}(\mathrm{X})=\mathrm{r}(\mathrm{X}+e)$ for all $e$ in Y , then $r(X \cup Y)=r(X)$

## A matroid is a hereditary system with an additional property

- A fourth such property is the augmentation property:
- if $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$ are independent sets with $\left|\mathrm{I}_{1}\right|>\left|\mathrm{I}_{2}\right|$, then $\mathrm{I}_{2}+e$ is independent for some $e$ in $\mathrm{I}_{1}-\mathrm{I}_{2}$

## A matroid is a hereditary system with an additional property

- A fourth such property is the augmentation property:
- if $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$ are independent sets with $\left|\mathrm{I}_{1}\right|>\left|\mathrm{I}_{2}\right|$, then $\mathrm{I}_{2}+e$ is independent for some $e$ in $\mathrm{I}_{1}-\mathrm{I}_{2}$
- Theorem 3.1.10 (Berge, 1957): A matching $M$ in a graph $G$ is a maximum matching in $G \Leftrightarrow G$ has no $M$-augmenting path
- so if G has an $M$-augmenting path then there is a matching $M^{\prime}$ with $\left|M^{\prime}\right|>|M|$ and $M^{\prime} \triangle M$ contains an $M$-augmenting path

## Transversal matroids from matchings in a bipartite graph

- For a bipartite graph, $\mathrm{G}=(\mathrm{U}, \mathrm{V}, \mathrm{E})$ let the elements of a matroid be the vertices in $U$ and the independent sets be sets of endpoints of matchings
- This matroid satisfies the augmentation property and is called a transversal matroid
- In the example above, the matroid is isomorphic to the kite with independent sets being acyclic subsets of edges

## Graphic matroids

- The cycle matroid of a graph, G , is the matroid with ground set $\mathrm{E}(\mathrm{G})$ and circuits (minimal dependent sets) given by the cycles of G
- A matroid that can be defined in this way is called a graphic matroid
- Not every matroid is graphic

## Vectorial matroids

- The ground set, E , is a set of vectors, $\left\{x_{i}\right\}$, in a vector space
- $\mathrm{I}=$ subsets of E that are linearly independent
- Dependent sets must have $\sum c_{i} x_{i}=0$ with some $c_{i}$ being nonzero
- Circuits are sets of $x_{i}$ with $\sum c_{i} x_{i}=0$ forcing all $c_{i} \neq 0$
- Not every matroid is vectorial
- The column matroid of this matrix is the cycle matroid of the kite:

| 0 | 0 | 0 | 1 | 1 |
| :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 1 | 0 | 1 |
| 1 | 1 | 0 | 0 | 0 |

## Uniform matroids and free matroids

- $U_{k, n}$ is the uniform matroid of rank $k$ defined on any ground set of size $n$ with bases being all of the subsets of size $k$
- so the independent sets are all of the subsets of size at most $k$
- If $n=k$ this is called the free matroid of rank $n$
- Uniform matroids may or may not be graphic and graphic matroids may or may not be uniform (Exercise 8.2.6 in West)

## Partition matroids

- If E is partitioned into distinct blocks $\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots \mathrm{E}_{\mathrm{k}}$, the partition matroid induced by this partition is the matroid with independent sets having at most one element in each block of the partition
- In a directed graph, each edge has a head and a tail, so the edges can be partitioned in two ways, called the head partition and the tail partition

## Matroids and greedy algorithms

- Matroids can be defined by the greedy algorithm property:
- For any nonnegative weight function on the ground set, the greedy algorithm selects an independent set of maximum total weight
- greedy ( matroid M ) returns: independent set I
$I \leftarrow$ empty; E $\leftarrow$ M.E;
while ( $E$ is nonempty) \{
$e \leftarrow$ an element of $E$ of maximum weight;
remove e from E ;
if $(I+e$ is independent) then $I \leftarrow I+e$;
\}
return I

## Matroids and matchings

- Given a bipartitite graph $\mathrm{G}=(\mathrm{U}, \mathrm{V}, \mathrm{E})$ it would seem natural to define a matroid by defining the independent sets to be the matchings of G
- This doesn’t always work (Exercises 8.2.1 and 8.2.2 in West)
- Suppose G is a directed graph with all edges directed from U to V, then any matching is contained in both the head partition and the tail partition
- This motivates the definition of the intersection of two matroids (which may not be a matroid)

## Matroid intersection

- Given matroids $\mathrm{M}_{1}$ and $\mathrm{M}_{2}$, with independent sets $\mathrm{I}_{1}$ and $\mathrm{I}_{2}$, $\mathrm{M}_{1} \cap \mathrm{M}_{2}$ is the hereditary system with independent sets being those sets that are independent in both $\mathrm{M}_{1}$ and $\mathrm{M}_{2}$
- Although $\mathrm{M}_{1} \cap \mathrm{M}_{2}$ is not a matroid in general, it does have the following property, proved by the Matroid Intersection Theorem:

$$
\max \left\{|\mathrm{I}|: \mathrm{I} \in \mathrm{I}_{1} \cap \mathrm{I}_{2}\right\}=\min \left\{\mathrm{r}_{1}(\mathrm{~A})+\mathrm{r}_{2}(\overline{\mathrm{~A}})\right\}
$$

where the min is over all subsets of the ground set and $\overline{\mathrm{A}}$ is the complement of A with respect to the ground set

- The matroid intersection algorithm (Papdimitriou and Steiglitz) solves this max-min problem in time $\mathrm{O}\left(|\mathrm{E}|^{3} \mathrm{C}(|\mathrm{E}|)\right)$ where $\mathrm{C}(|\mathrm{E}|)$ is the time required for matroid queries

## Problems with intersections of more than two matroids

- Intersecting more than two matroids can lead to NP-complete problems, so there's not much hope for a polynomial-time algorithm for solving matroid intersection problems of higher order
- Papadimitriou and Steiglitz show how to define the Hamiltonian path problem as the intersection of three matroids

## The (weak) elimination property

- The weak elimination property :
- If $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$ are distinct circuits and $x \in \mathrm{C}_{1} \cap \mathrm{C}_{2}$ then there is another circuit contained in $\mathrm{C}_{1} \cup \mathrm{C}_{2}-x$

## The (weak) elimination property

- The weak elimination property :
- If $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$ are distinct circuits and $x \in \mathrm{C}_{1} \cap \mathrm{C}_{2}$ then there is another circuit contained in $\mathrm{C}_{1} \cup \mathrm{C}_{2}-x$
- There must be a strong elimination property :
- If $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$ are circuits with $x \in \mathrm{C}_{1} \cap \mathrm{C}_{2}$ and $x_{1} \in \mathrm{C}_{1}-\mathrm{C}_{2}$ then there is another circuit containing $x_{1}$ contained in $\mathrm{C}_{1} \cup \mathrm{C}_{2}-x$

## Submodularity of the rank function

- M is a matroid if its rank function is submodular :
- for any two subsets, X and Y , of the ground set

$$
r(X \cap Y)+r(X \cup Y)=r(X)+r(Y)
$$

- This is related to the dimension formula for subspaces of a vector space:
- $\operatorname{dim}(U \cap V)+\operatorname{dim}(\operatorname{span}(U \cup V))=\operatorname{dim}(U)+\operatorname{dim}(V)$ where U and V are subspaces of a vector space

## Alternative definition of transversal matroids

- Suppose the ground set E is the union of $m$ sets $\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots \mathrm{~A}_{m}$
- The transversal matroid induced by these sets can be defined via an $\mathrm{E},[m]$ bipartite graph with edges $(e, i)$ whenever $e \in \mathrm{~A}_{i}$
- The independent sets of this matroid are the subsets of $E$ that are saturated by matchings in this bipartite graph
