

In Impcore, a name stands for a value

Environment associates each **variable** with one **value**

Written $\rho = \{x_1 \mapsto n_1, \dots, x_k \mapsto n_k\}$,
associates variable x_i with value n_i .

Environment is **finite map**, aka **partial function**

$x \in \text{dom } \rho$ x is defined in environment ρ

$\rho(x)$ the value of x in environment ρ

$\rho\{x \mapsto v\}$ extends/modifies environment ρ to map x to v

Find behavior using environment

Recall

`(* y 3) ; ; what does it mean?`

Impcore uses three environments

Global variables ξ (“ksee”)

Functions ϕ (“fee”)

Formal parameters ρ (“roe”)

There are **no local variables**

- Just like `awk`; if you need temps, use extra formal parameters
- For homework, you’ll add local variables

Function environment ϕ not shared with variables—just like Perl

Syntax & environments determine meaning

Initial state of abstract machine:

$$\langle e, \xi, \phi, \rho \rangle$$

State $\langle e, \xi, \phi, \rho \rangle$ is

- e Expression being evaluated
- ξ Values of global variables
- ϕ Definitions of functions
- ρ Values of formal parameters

Three environments make a **basis**

Meaning expressed as “Evaluation judgment”

We say

$$\langle e, \xi, \phi, \rho \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle$$

(Big-step judgment form.)

Notes:

- ξ and ξ' may differ
- ρ and ρ' may differ
- ϕ must equal ϕ

Exercise: what do we know about globals, functions?

Primes and not primes

A prime says “**something might change**”
(Impcore: value of a variable)

Primes are:

- Always in the *form of judgment*:

$$\langle e, \xi, \phi, \rho \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle$$

- Often in *judgments*
- Usually in *rules*
- **Never** in a “derivation” (computation)

Prime implies “we don’t know”

Impcore atomic form: literal

“Literal” generalizes “numeral”

LITERAL

$\langle \text{LITERAL}(v), \xi, \phi, \rho \rangle \Downarrow \langle v, \xi, \phi, \rho \rangle$

We know nothing changes!

(Numeral converted to $\text{LITERAL}(v)$ in parser)

Impcore atomic form: variable name

Parameters hide global variables.

FORMALVAR

$$x \in \text{dom } \rho$$

$$\langle \text{VAR}(x), \xi, \phi, \rho \rangle \Downarrow \langle \rho(x), \xi, \phi, \rho \rangle$$

GLOBALVAR

$$x \notin \text{dom } \rho \quad x \in \text{dom } \xi$$

$$\langle \text{VAR}(x), \xi, \phi, \rho \rangle \Downarrow \langle \xi(x), \xi, \phi, \rho \rangle$$

Impcore compound form: assignment

In $\text{SET}(x, e)$, e is any expression

FORMALASSIGN

$$\frac{x \in \text{dom } \rho \quad \langle e, \xi, \phi, \rho \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle}{\langle \text{SET}(x, e), \xi, \phi, \rho \rangle \Downarrow \langle v, \xi', \phi, \rho' \{x \mapsto v\} \rangle}$$

GLOBALASSIGN

$$\frac{x \notin \text{dom } \rho \quad x \in \text{dom } \xi \quad \langle e, \xi, \phi, \rho \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle}{\langle \text{SET}(x, e), \xi, \phi, \rho \rangle \Downarrow \langle v, \xi' \{x \mapsto v\}, \phi, \rho' \rangle}$$

Impcore can assign only to **existing** variables

Semantics corresponds to code

We compose rules to make proofs

<i>Math</i>	<i>Code</i>
Semantics	Interpreter
Evaluation judgment	Result of evaluation
Proof of judgment	Computation of result
Rule of semantics	Case in the interpreter

Interpreter succeeds if and only if a proof exists

(Homework: result is unique!)

Implementing variables: two rules

FORMALVAR

$$x \in \text{dom } \rho$$

$$\langle \text{VAR}(x), \xi, \phi, \rho \rangle \Downarrow \langle \rho(x), \xi, \phi, \rho \rangle$$

GLOBALVAR

$$x \notin \text{dom } \rho \quad x \in \text{dom } \xi$$

$$\langle \text{VAR}(x), \xi, \phi, \rho \rangle \Downarrow \langle \xi(x), \xi, \phi, \rho \rangle$$

How do we tell them apart?

Implementing evaluation (VAR): three cases

Consult formals ρ or globals ξ :

```
switch (e->alt) {
  case VAR:
    if (isvalbound(e->u.var, formals))
      return fetchval(e->u.var, formals);
    else if (isvalbound(e->u.var, globals))
      return fetchval(e->u.var, globals);
    else
      runerror("unbound variable %n", e->u.var);
  ...
}
```

Why a third case?

- When no proof, run-time error

Application math: user-defined function

APPLYUSER

$$\phi(f) = \mathbf{USER}(\langle x_1, \dots, x_n \rangle, e)$$

x_1, \dots, x_n **all distinct**

$$\langle e_1, \xi_0, \phi, \rho_0 \rangle \Downarrow \langle v_1, \xi_1, \phi, \rho_1 \rangle$$

$$\langle e_2, \xi_1, \phi, \rho_1 \rangle \Downarrow \langle v_2, \xi_2, \phi, \rho_2 \rangle$$

\vdots

$$\langle e_n, \xi_{n-1}, \phi, \rho_{n-1} \rangle \Downarrow \langle v_n, \xi_n, \phi, \rho_n \rangle$$

$$\langle e, \xi_n, \phi, \{x_1 \mapsto v_1, \dots, x_n \mapsto v_n\} \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle$$

$$\langle \mathbf{APPLY}(f, e_1, \dots, e_n), \xi_0, \phi, \rho_0 \rangle \Downarrow \langle v, \xi', \phi, \rho_n \rangle$$

Simpler math: function of two parameters

APPLYUSER

$$\phi(f) = \text{USER}(\langle x_1, x_2 \rangle, e)$$

x_1, x_2 **distinct**

$$\langle e_1, \xi_0, \phi, \rho_0 \rangle \Downarrow \langle v_1, \xi_1, \phi, \rho_1 \rangle$$

$$\langle e_2, \xi_1, \phi, \rho_1 \rangle \Downarrow \langle v_2, \xi_2, \phi, \rho_2 \rangle$$

$$\langle e, \xi_2, \phi, \{x_1 \mapsto v_1, x_2 \mapsto v_2\} \rangle \Downarrow \langle v, \xi', \phi, \rho' \rangle$$

$$\langle \text{APPLY}(f, e_1, e_2), \xi_0, \phi, \rho_0 \rangle \Downarrow \langle v, \xi', \phi, \rho_2 \rangle$$

Evaluating function application

The math demands these steps:

- Find function in ϕ environment

```
f = fetchfun(e->u.apply.name, functions);
```

- Using caller's ρ , evaluate actuals

```
vs = evallist(e->u.apply.actuals, globals, functions,  
             formals);
```

N.B. actuals evaluated in current environment

- **Make a new environment:** bind formals to actuals

```
new_formals = mkValenv(f.u.userdef.formals, vs);
```

- Evaluate body in new environment

```
return eval(f.u.userdef.body, globals, functions,  
           new_formals);
```

Next up: Good and bad judgments

Which judgments describe real computations?

Your turn: good and bad judgments

Which *correctly* describes what happens at run time?

1. $\langle (+\ 2\ 2), \xi, \phi, \rho \rangle \Downarrow \langle 4, \xi, \phi, \rho \rangle$
2. $\langle (+\ 2\ 2), \xi, \phi, \rho \rangle \Downarrow \langle 99, \xi, \phi, \rho \rangle$
3. $\langle (+\ 2\ 2), \xi, \phi, \rho \rangle \Downarrow \langle 0, \xi, \phi, \rho \rangle$
4. $\langle (\text{while } 1\ 0), \xi, \phi, \rho \rangle \Downarrow \langle 77, \xi, \phi, \rho \rangle$
5. $\langle (\text{begin } (\text{set } n\ (+\ n\ 1))\ 17), \xi, \phi, \rho \rangle$
 $\Downarrow \langle 17, \xi, \phi, \rho \rangle$

To know for sure, we **need a proof**

Judgment speaks truth when “derivable”

Special kind of proof: **derivation**

- It's a data structure (**derivation tree**)
- Made inductively, by composing rules
- **Valid** derivation matches rules (by substitution)
- Spacelike representation of timelike behavior
(think **flip-book animation**)

A form of “syntactic proof”

Recursive evaluator travels inductive proof

Root of derivation at the **bottom** (surprise!)

Build

- Start on the left, go up
- Cross the ↓
- Finish on the right, go down

The “Tony Hawk” algorithm

First let's see a movie

Evaluating $(10 + 1) \times (10 - 1)$

$\langle (* (+ 10 1) (- 10 1)), \xi, \phi, \rho \rangle \Downarrow$

Evaluating $(10 + 1) \times (10 - 1)$

Algorithm for building derivations

Want to solve

$$\langle e, \xi, \phi, \rho \rangle \Downarrow ?$$

What rule can I use to prove it?

1. **Syntactic form** of e narrows to a few choices
(usually 1 or 2)
2. Look for form in **conclusion**
3. Now check **premises**
4. When premise is evaluation judgment,
build sub-derivation recursively

Derivation is written \mathcal{D}
