Instructions

This exam contains 14 pages, including this one. Make sure you have all the pages. Write your name on the top of this page before starting the exam.

Write your answers on the exam sheets. If you finish at least 15 minutes early, bring your exam to the front when you are finished. Otherwise, wait until the end of the exam to turn it in. Please be as quiet as possible.

If you have a question, raise your hand. If you feel an exam question assumes something that is not written, write it down on your exam sheet. Barring some unforeseen error on the exam, however, you shouldn’t need to do this at all, so be careful when making assumptions.

Question 1. Short Answer (20 points).

a. (5 points) In his paper, Parnas listed three potential categories of benefits of software modularity: managerial, product flexibility, and comprehensibility. Explain briefly how two of these benefits could arise from modularity.

Answer:
Managerial—different groups can work on different modules with less communication.
Product flexibility—developers can change one module without changing another.
Comprehensibility—the system can be understood one module at a time.

b. (5 points) Briefly explain the difference between confidentiality and integrity.

Answer:
Confidentiality means a system protects private information from release to adversaries.
Integrity means a system protects its internal information from being modified by adversaries.
c. (5 points) In Brooks’s essay *No Silver Bullet...*, what does “silver bullet” refer to?

Answer:

From the paper: “But, as we look to the horizon of a decade hence, we see no silver bullet. There is no single development, in either technology or management technique, which by itself promises even one order of magnitude improvement in productivity, in reliability, in simplicity.”

---

d. (5 points) Consider the following ethical situation. Blocker Plus is a content filter that blacklists web sites not suitable for children. Blocker Plus does not disclose how it decides which sites to block, but in fact it uses machine learning to automatically identify inappropriate content. Recently, the developers found their technology is blocking violent web sites (as its users would like), but users are complaining that it is blocking web sites about vaccinations. Weighing the tradeoffs, and without justification to its users, the company selling Blocker Plus decides not to change their product despite the complaints.

List one ethical principle Blocker Plus is following, and one ethical principle Blocker Plus is violating. Explain your answers very briefly (1-2 sentences each). Only refer to principles in Part 1 of the ACM Code of Ethics.

Answer:

Any plausible answer is okay. The system mostly adheres to 1.1, Contribute to Society, by helping solve a societal problem. The system violates 1.2, Avoid Harm, by blocking critical information, and 1.3, Be Honest and Trustworthy, by not being transparent about their technology.
**Question 2. Design Patterns (20 points).** In the *command pattern*, command objects represent actions. For example, here is a UML diagram (from the Design Patterns book) showing the command pattern for a word processing app. There is an interface, *Command*, with four implementations for the paste, font, save, and quit commands:

![UML diagram](image)

We will use this idea to implement undo-able cut and paste commands for a text editing program. Here are the program's APIs:

```java
public class State {
    public static StringBuffer doc; /* The text document */
    public static String buffer; /* The paste buffer */
}
```

Below, you will develop *Cut* and *Paste* commands. For example:

```java
State.doc = "abcdefgh"
c = new Cut(3, 5);
c.execute(); // doc = "abcfgh" and buffer = "de"
p = new Paste(0);
p.execute(); // doc = "deabcfgh" and buffer = "de"
p.undo(); // doc = "abcfgh" and buffer = "de"
c.undo(); // doc = "abcdefgh" and buffer = "de"
```

In the questions below, \( n \) and \( m \) are non-negative integers, and position 0 is the position of the first character in `doc`. Assume that your cut and paste commands will be executed exactly once, and will be undone at most one time and in the correct sequence (e.g., if `undo` is called on two different commands, the calls will be in the reverse order the commands were executed in). You'll probably need the following methods:

```java
class StringBuffer {
    void delete(int start, int end); // Removes substring from start to end−1, inclusive
    void insert(int offset, String s); // Inserts s at offset
    String substring(int start, int end); // Returns substring from start to end−1, inclusive
}
```
a. (6 points) Implement a Paste command such that new Paste(n) creates a command whose execute method inserts the contents of buffer at position n in doc, and its undo method reverses the action.

```java
class Paste implements Command {
    int n;
    int pastedSize;
    Paste(int n) {
        this.n = n;
    }
    void execute() {
        State.doc.insert(n, State.buffer);
        pastedSize = State.buffer.length();
    }
    void undo() {
        State.doc.remove(n, n + pastedSize);
    }
}
```

b. (6 points) Implement a Cut command such that new Cut(n, m) creates a command whose execute method removes the contents of buffer from n to m-1, inclusive, and stores the removed text in buffer. Its undo method reverses the action. You can assume n and m are in-bounds.

```java
class Cut implements Command {
    int n, m;
    String removed;
    Cut(int n, int m) {
        this.n = n;
        this.m = m;
    }
    void execute() {
        removed = State.doc.substring(n, m);
        State.doc.remove(n, m);
    }
    void undo() {
        State.doc.insert(n, removed);
    }
}
```
c. (8 points) Suppose you wanted to make two changes to the Command interface:

1. Add a redo() operation to Command that reapplys a command that was undone.

2. Add checks (assertions) to ensure that execute, undo, and redo operations are called in a sensible order. For example, suppose $a = \text{new Cut(...)}$, $b = \text{new Paste(...)}$, $c = \text{new Cut(...)}$. Then calling $a$.execute(); $b$.execute(); $c$.execute(); $c$.undo(); $b$.undo(); $b$.redo(); makes sense. But calling $a$.execute(); $b$.execute(); $a$.undo(); or $a$.execute(); $a$.redo(); or $a$.execute(); $a$.execute(); do not make sense.

Describe, in English, how you would need to change Cut and Paste above to support these changes.
(This page intentionally left blank)
Question 3. Testing and Reflection (20 points). Using Java’s dynamic proxy facility, write a class \texttt{Recorder} that can be used to wrap an object in a proxy that records all calls to the object and subsequently emits (to stdout) Java source code that can be used to replay those calls.

For example, suppose we have the following code:

```java
interface I {
    void m(int a, int b);
}

class A implements I {
    void m(int a, int b) { System.out.println("a=\" + a + ",b=\" + b; }
}
```

Here is an example use of the \texttt{Recorder} class:

```java
A a = new A();
Recorder r = new Recorder(a, I.class); // Create recorder object
I wrapped = (I) r.getProxy(); // Get the stand−in for a
wrapped.m(1, 2); // Records call, then prints "a=1,b=2"
wrapped.m(3, 4); // Records call, then prints "a=3,b=4"
r.printTest(); // Prints the following four lines:
    // void test (I o)
    // o.m(1, 2);
    // o.m(3, 4);
    // }
```

- Don’t worry about exceptions from reflection, and you can assume all preconditions are satisfied.
- Calling \texttt{new Recorder(o, c)} creates a new recorder object, where \texttt{o} is the underlying object to record method calls to, and \texttt{c} is an interface it implements.
- If \texttt{r} is a \texttt{Recorder}, calling \texttt{r.getProxy()} returns an object \texttt{proxy} that implements \texttt{c}. Calling \texttt{r.getProxy()} multiple times always returns the same object.
- Invoking methods on \texttt{proxy} first records (internal to \texttt{r}) the called method name and arguments. Then it delegates to \texttt{o} and returns the result. You can assume that all arguments are integers.
- Calling \texttt{r.printTest()} prints, to standard output, source code of a method \texttt{test} that takes one argument that implements \texttt{c} and invokes the recorded method calls, in the same order of the calls and with the same arguments.
- You can use any part of the Java standard library. You’ll probably want to use the methods below.
- Write your answer on the next page.

```java
class Class {
    String getName();
}
class Method {
    Object invoke(Object obj, Object[] args); // invoke this method on obj with args
}
interface InvocationHandler {
    Object invoke(Object proxy, Method method, Object[] args); // Processes an invocation of method on proxy with args
}
class Proxy {
    // Return a proxy for iface that dispatches method invocations to h. (We’ve simplified this method a bit.)
    static Object newProxyInstance(Class iface, InvocationHandler h);
}
class LinkedList<E> { boolean add(E e); /* appends e to the end of the list */ }
```
import java.lang.reflect.*;
import java.util.*;

public class Recorder implements InvocationHandler {

    List<String> log = new LinkedList<String>();
    private Object base;
    private Class interface;

    Recorder(Object base, Class interface) {
        this.base = base;
        this.interface = interface;
    }

    private Object theProxy;
    public Object getProxy() {
        if (theProxy == null) {
            theProxy = Proxy.newProxyInstance(interface, new Recorder(o));
        }
        return theProxy;
    }

    Object invoke(Object proxy, Method m, Object[] args) {
        String sargs = "";
        for (Object o: args) {
            if (sargs != "") {
                sargs += ",";
            }
            sargs += ((Integer) o).toString();
        }
        log.add("o." + m.name() + "(" + sargs + ");");
        m.invoke(base, args);
    }

    void printTest () {
        System.out.println("void test (\" + interface.getName() + " o) {
    ");
        for (String line : log) {
            System.out.println(line);
        }
        System.out.println("}");
    }
}

Question 4. Program Verification (10 points).

a. (3 points) In the following code, B is a subclass of A. Are the preconditions of m appropriate for the subclass relationship, according to the Liskov substitution principle? Explain why or why not. Your example should explain briefly in English using a concrete example of calling m.

```java
class A {
    // precondition : x < y
    void m(int x, int y) { ... }
}

class B extends A {
    // precondition : 0 < x < y
    void m(int x, int y) { ... }
}
```

Answer: No. Given an A a, we could invoke a.m(-4, 10) according to the precondition on A#m. But a could actually be a B based on subclassing, and that call would violate B#m's precondition.

b. (3 points) In the following code, B is a subclass of A. Are the postconditions of m appropriate for the subclass relationship, according to the Liskov substitution principle? Explain why or why not using a concrete example. Ignore the possibility of integer overflow.

```java
class A {
    // postcondition : ret > 0
    int m(int x) { ... }
}

class B extends A {
    // postcondition : ret > x*x
    int m(int x) { ... }
}
```
c. (2 points) In the following code, B is a subclass of A. For B to be a subclass of A according to the Liskov substitution principle, should we have Exn1 extends Exn2 or Exn2 extends Exn1? Explain briefly.

```java
class A {
    int m(int x) throws Exn1 { ... }
}
class B extends A {
    int m(int x) throws Exn2 { ... }
}
```

Answer: We need Exn2 extends Exn1. Given an A a, a caller that invokes a.m(...) can handle an Exn1, and therefore they can handle any subclass of Exn1.

d. (2 points) Use the assignment rule to compute the weakest precondition of the following assignment statement and postcondition. (In other words, fill in the ?.)

```java
{ ? } x = y + 2; { x > z }
```
Question 5. Refactoring (10 points). Consider the following code:

```java
public class Rental {
    private Movie _movie;
    private int _daysRented;

    public Rental(Movie movie, int daysRented) {
        _movie = movie;
        _daysRented = daysRented;
    }

    public int getDaysRented() { return _daysRented; }
    public Movie getMovie() { return _movie; }

    public double amountFor() {
        double thisAmount = 0;
        //determine amounts for each line
        switch (getMovie().getPriceCode()) {
            case Movie.REGULAR:
                thisAmount += 2;
                if (getDaysRented() > 2)
                    thisAmount += (getDaysRented() - 2) * 15;
                break;
            case Movie.NEW_RELEASE:
                thisAmount += getDaysRented() * 3;
                break;
            case Movie.CHILDRENS:
                thisAmount += 1.5;
                if (getDaysRented() > 3)
                    thisAmount += (getDaysRented() - 3) * 1.5;
                break;
        }
        return thisAmount;
    }
}

public class Movie {
    public static final int CHILDRENS = 2;
    public static final int REGULAR = 0;
    public static final int NEW_RELEASE = 1;

    private String _title;
    private int _priceCode;

    public Movie(String title, int priceCode) {
        _title = title;
        _priceCode = priceCode;
    }

    public int getPriceCode() { return _priceCode; }
    public void setPriceCode(int arg) { _priceCode = arg; }
    public String getTitle() { return _title; }
}
```
Describe at least two different refactorings we could perform on the sample code, and explain why those refactorings are useful. Your refactorings should be different not just in what source code they operate on but what they actually do (e.g., don’t list three uses of Move Method). You may not use renaming of variables, methods, or fields by themselves as refactorings. You may use any reasonable refactoring, not just those we discussed in class. Don’t worry about getting the names exactly right.

1. Add parameter daysRented to replace call to getDaysRented() in amountFor(), in preparation for step 2.
2. Move method amountFor() from Rental into Movie, since this will differ from one kind of movie to another.
3. Replace conditional switch by polymorphism by replacing the single class Movie by three subclasses ChildrensMovie, RegularMovie, and NewRelease. Split the behavior of the amountFor() method accordingly. This refactoring has many advantages. For example, it means we have an enumerate of movies rather than using an integer type; it’s easy to add new movies using subclassing.
Question 6. Delta Debugging (20 points). Suppose we have a class with a method \texttt{test} that takes a string \texttt{s} and returns \texttt{true} if \texttt{s} passes the test and \texttt{false} otherwise:

```java
class A {
    public static boolean test(String s) {
        // Returns true if s passes, false if it fails
    }
}
```

Implement a method \texttt{String dd(String init)} that takes a string \texttt{init} such that \texttt{A.test(init) == false} and minimizes it, using the delta debugging algorithm from class and returning the minimal string. For example, if the body of \texttt{test} were \texttt{return !s.contains("abc")}, then \texttt{dd("123456abc78901")} would return \texttt{"abc"}, using a sequence of calls to \texttt{test} like the following. (Your code doesn’t need to follow this exact sequence.)

<table>
<thead>
<tr>
<th>A.test(&quot;bc78901&quot;)</th>
<th>passes, try other half</th>
<th>A.test(&quot;c7&quot;)</th>
<th>passes</th>
</tr>
</thead>
<tbody>
<tr>
<td>A.test(&quot;123456a&quot;)</td>
<td>passes, increase granularity</td>
<td>A.test(&quot;ab&quot;)</td>
<td>passes, increase granularity</td>
</tr>
<tr>
<td>A.test(&quot;456abc78901&quot;)</td>
<td>fails, now have a smaller test</td>
<td>A.test(&quot;bc7&quot;)</td>
<td>passes</td>
</tr>
<tr>
<td>A.test(&quot;c78901&quot;)</td>
<td>passes</td>
<td>A.test(&quot;ac7&quot;)</td>
<td>passes</td>
</tr>
<tr>
<td>A.test(&quot;456ab&quot;)</td>
<td>passes, increase granularity</td>
<td>A.test(&quot;abc&quot;)</td>
<td>fails, now have a smaller test</td>
</tr>
<tr>
<td>A.test(&quot;abc78901&quot;)</td>
<td>fails, now have a smaller test</td>
<td>A.test(&quot;bc&quot;)</td>
<td>passes</td>
</tr>
<tr>
<td>A.test(&quot;8901&quot;)</td>
<td>passes</td>
<td>A.test(&quot;ac&quot;)</td>
<td>passes</td>
</tr>
<tr>
<td>A.test(&quot;abc7&quot;)</td>
<td>fails, now have a smaller test</td>
<td>A.test(&quot;ab&quot;)</td>
<td>passes, can’t increase granularity</td>
</tr>
</tbody>
</table>

Hint. You’ll definitely want to use \texttt{String} methods \texttt{int length()} and \texttt{String substring(int beginIndex, int endIndex)}. The latter returns the substring beginning at \texttt{beginIndex} and ending at \texttt{endIndex} - 1, inclusive.

Hint. Use integer arithmetic throughout and don’t worry about rounding issues. (The algorithm is very robust and will work fine.)

```java
class DeltaDebug {
    public static String dd(String init) {
        // Your implementation here
    }
}
```
